1 pricklypear.borg

pricklypear

A multi-user Lisp operating system in the Smalltalk tradition: OCaml image binary, Postgres object store, htmx UI. Many humans, each with session + personal garden. One binary serves all sessions (single-image.borg); the multi-user product is auth.multi-user-product; isolation is multi-user.cotenant-isolation – session + branch scoped, one process.

[status: partial]

> – *agent note:* 2026-08-02 full-book status reconcile: root stays partial while open chapter work remains (notes partials, dabar search-fts, image repl-exp/per-req, auth argon2/ssh-repl, branching schema/ast-nodes, multi-user permissions, object-model type-system, one-tree migration, migrations branching-interaction, structural-editing ast-view, formal-verification planned). borge report after pass ~149 implemented / 4 planned / ~96%. See docs/plans/borge-status-reconcile-checklist.md.

> *[verify] build: dune build @all – exit 0 (lisp + common + image); test: dune runtest – alcotest across lisp/common/image (some prim edge cases may fail; track separately); smoke: scripts/dev.sh start boots PG + single image; curl /health and /login; smoke: python3 scripts/auth_product_smoke.py against PP_HTTP_PORT*

> – *agent note:* 2026-08 drift declaration pass (BORGE-1786035030): docs/ orphans excused with reasons. These are scratch plans, contracts, and generated artifacts – not spec'd features. Declare in a chapter only if a feature grows around one.

> – *roerick:* An introduction: A little about me:
>
> I'm super excited about what has emerged with Pricklypear. Pricklypear is the result of a kind of long, meandering journey. I see a lot of these cactus on my hike. In the middle of the desert, they are common, they are prickly, and they bear delicious fruit. I've also been told you can use them to harvest water kefir yeast, but I've yet to confirm this.
>
> I quit my development job and now work at a dentist office and a restaurant. But I just can't seem to stop coding. For a while I was trying to make the ultimate "CRUDmonkey" platform. Basically, I spent a lot of time with half baked designs trying to reinvent web frameworks. Then, I became totally taken with the idea of a tree-based structure editor.
>
> My background is largely as a python CRUDmonkey, hence my interest in reinventing frameworks. I did a lot of data processing elbow grease work. I was CTO of a 13 person startup for a while.

When I left that job I was pretty burnt out. I didn't think I enjoyed programming, but I still was obsessed with the idea of maybe I could make it easier.

Then I found OCaml. Functional programming did it for me, man. It was like learning to program all over again. I started learning about all the things I had basically ignored as a python guy. I learned about compilers, low level languages. I took a freelance gig doing static analysis on IBM HLASM assembly language.

The only thing I really wanted from code? I wanted to build my dream zettelkasten. I just wanted a good notes app for my bible study. First I built a bible mode in Obsidian with markdown files. But as soon as I tried to get Strong's Concordance in there, I absolutely hit the limits of what Obsidian could do. Then, I decided to switch over to elisp. LLMs were barely functional at this time, and they were really bad at lisp. This was the "copy and paste from ChatGPT" era. My emacs / org-roam zettelkasten worked amazingly. Honestly, I love emacs and I love org-roam. Absolutely beautiful pieces of software. I also love the sense of calm that I get with emacs software. I pulled up this bible app in emacs 4 years later and it just... worked. Amazingly. None of the constant churn of the JS ecosystem.

OK, so then I got into OCaml, and I was very anti LLM. They didn't work, they made you dumb, they were a scam, yada yada yada. So I built myself a bible app, all by hand, in OCaml / Dream. I had a great time with this. I felt like I probably learned more about Dream than I did OCaml, but that's how I felt when I first learned Python also.

Then I took a gig with some guys who were doing IBM mainframe LLM stuff. I started coding in TypeScript (which i had never really used), right around the time when the LLMs got really, really good. Like November of 2025? I saw a massive increase in their ability to compose and build code.

Then I went deep. I started building harnesses, orchestrators, I did the full LLM psychosis thing. I eventually settled on my Borge architecture. Without going too deeply into it, it's a DSL for defining spec and a series of CLI tools to get agents to implement, review, and build out that spec. I'm not sure it's any more efficient but it seems to work super well for me.

So then one day I had the brainwave. Can I make an interpreted lisp where the functions are stored in postgres? The agent assured me I was a genius yet again, but I had a good feeling about this one. I had the LLM draw out my Borge spec, and then started a ralph loop. I think it went for like, 25 iterations? It ran for 4 days and it crashed a couple times and I think I maxed out three different providers. It used a lot of tokens. I got an email from one of my LLM providers the next day letting me know they were tripling their costs.

When I started playing with it, I actually couldn't figure out how to use it at first. I had the agent draw up a intro guide. Then I realized that not only did it work, I could write language functions to the database, but that also those functions were working as web endpoints. I realized I had a whole framework.

It worked so well. I built a couple apps on top, it was effortless. I plugged an LLM into the system. Once I prompted it to realize Pricklypear was not a cactus in this scenario, it completely understood the harness it was in and it just... started writing functions.

I couldn't believe it. Then I gave my local LLM access to the full REPL, and I realized I wouldn't ever have to build an API or CLI interface for agents ever again.

I'm delighted by this. I have wanted a Smalltalk type environment since I learned about what that was. But by incredible, happy accident, I also got my brand spanking new web framework, and I also got my tree based editor. I honestly feel, I don't need any more software. I'd be good. If I had my druthers, I would just work on this in private and read Functional Programming papers and Alonzo Church in my hammock for the next 5 years while I dogfood this thing. But, you know, "building in public" and all that.

I'm hoping some people are as thrilled and inspired by this as I am. Maybe the code is useful, or maybe just hearing about the concept is enough to inspire people. Or maybe, and this may be more likely, nobody will give a crap. I don't know where LLMs will go in the future, but I am really happy right here.

I'll let the agent describe the system here for a bit, and then talk about why I think this system is really, really good.

– *roerick:* Alright - I'll talk a little bit about what I think Pricklypear is good at, and where I see it going

A lot of people have talked about how incredible Lisp is. Personally, I'm not totally sold. Don't get me wrong, lisp is wonderful. But I think for larger projects you just need static typing. I didn't like static typing for a long time, I totally get it. But for medium or big projects, I just don't know how you do big refactors without it.

That said, I think Lisp is like Ruby a lot, it's a beautiful and expressive language. So this is a lisp machine. And I think it's good for the same types of programs that Ruby is good at. So I did my best to clone Basecamp, hah.

Having an agent work with a REPL is incredible. I mean, it's spectacular. They can define functions. They can read and execute individual functions. They can build functions inside out or bottom up. They can build them top down. They can SSH in remotely and access the REPL while they're developing. It's pretty tight.

I don't think any other architecture can match Pricklypear for building web apps, and I honestly don't think it's even close. All of those LLM marketing idiots telling you about on-demand self healing software? Hey, this is it. It's right here. I don't think you can do this with any other stack? Maybe like erlang or something.

The future I see for Pricklypear or something like it is enabling LLMs to build on demand software for small and medium businesses. I don't even think you need to have a Pricklypear guy on staff? I mean you could, it'd probably help. But I think literally users can ask for features and they will be deployed. I've had some trouble getting the built-in agent to build out like a whole app from start to finish, but it can certainly add features. And that loop is closing fast.

I'm biased and deep in AI psychosis, but I'm telling you this is a much bigger leap than OpenClaw. Oh, you put your little crab agent inside a chat bot? Guess what? Mine lives inside a language which he is developing himself, and that language is also a fully baked web app. (Sorry, OpenClaw is brilliant, but I had to. You'll understand when you login the first time.)

Let's talk roadmap. I'm going to dogfood this thing for a while. Maybe some other people will do something similar. I don't really feel any obligation to build anything for anybody else. Get your own! But, I would like to get this thing to the point where it's functioning as a self contained unit, and like, my dad could hop on it and he wouldn't have to learn anything about Lisp Machines in order to use it. I think this is feasible. It's just a weird little platform to build apps on.

I'm hoping to get those apps fleshed out a bit. This is my new homelab center. I'm moving my life onto this thing. It's too good not to. So I'd like for those apps to feel really really good. Currently, they do not feel great. They are not cozy. I want calm, and I want cozy. Even though I can change these apps every day - I want to run them without changes for 5 years.

I initially spec'd this out to run on MirageOS, but we've scrapped that for now. I would like to make this happen eventually. For now, I remain an OpenBSD guy. If you want Linux compatibility, make your agent do it. (I use Arch for development, btw). So I think self contained image is a priority.

I would like to get some academic grounding on building this Lisp out. I don't know nothin about languages. Seriously. I just added floats to this thing. Also I think the language itself is called Nopales, but that isn't reflected anywhere right now. There is some sort of rudimentary effects system. I have no idea how it works. I don't really understand the subtleties of async, and the OCaml landscape is pretty confusing.

On a similar note, I'd like to get some education on formal proofs in software. I think that it is absolutely work spending some time trying to add formal verification to the OCaml outershell of Pricklypear. Lisp gives a great surface for the LLM on top, and I'm perfectly happy with a little jank there, but the core really should be incredibly stable.

I want to really polish up the node editor and the code editor. It should be a first class experience. Keyboard shortcuts, node navigation. I want it to feel as good as vim.

I'd like to see local-first LLMs, too. You really don't need much here. And the way it's designed, it would plug right into a local agent. That local agent really wants to generate his own lisp functions using a recursive bottom up function generator call!

OK, that's enough for now. This is about as much sharing as I do, generally speaking. I guess I could get on Twitter and try to shill this thing but I think I'd rather just build it instead.

philosophy

philosophy

Design principles for the single-image habitat
[status: implemented]

> *[verify] build: dune build @all; smoke: one image process + Postgres object store + htmx UI*

These principles describe the system as it runs today: one unix image binary, Postgres as durable store, Nopales product shell, multi-user via sessions and branches.

Historical multi-process / Mirage-fleet language lived here in early drafts; that topology is retired. Solo5 and process isolation remain optional later hardening (see spikes/), not v1 product claims.

1. One live image. The running OCaml process is the OS surface: HTTP, REPL, eval, auth. No supervisor fleet or authd sidecar in the hot path. Rebuild from git + Postgres rows; do not treat the process as the disk.

2. Postgres is the filesystem. All durable state is rows (function_defs, type_defs, view_bindings, data_rows, auth, AI sessions, ?). The image is ephemeral and rebuildable from the store + package seed.

3. Lisp-1, homoiconic. The AST is the source. Functions persist as JSONB. Editing the AST is editing the code. Closures, let, lambda, application are first- class. Macros (defmacro + quasiquote) are specified under lisp-interpreter.macros – unhygienic v1 with gensym; expand at use and at define/load; store source AST with macro call sites.

4. Two-tier change model. OCaml (primitives, HTTP, store, auth gate) changes slowly via rebuild/deploy. Nopales (user functions AND product environment UI – nav, home, routes, theme) changes fast via row updates. OCaml must not ship a silent second product skin; host/gate/emergency only (image.system-browser).

5. Branches, not namespaces. system/main is the package baseline; each user has username/personal as an inheriting garden. Code branches; shared data. Fork is cheap; merge/promote is the careful operation.

6. Multi-user by session and branch. Isolation is not per-process unikernels in v1. Many humans share one image; identity + branch scope their code world. Stronger process isolation is a later product choice.

7. Author-runs-as-author. A function executes with its author's data permissions where that model applies – honest setuid-shaped provenance, not caller-spoofing.

8. SERIALIZABLE by default. Mutating store paths default to SERIALIZABLE transactions. Weaker isolation is opt-in; most Nopales never sees the dial.

9. Additive-only schema evolution. Types and migrations grow; they do not casually drop or rename. Cruft may accumulate; correctness and simple deploys matter more.

10. Inspectability is non-negotiable. Functions, types, branches, routes, rows, and sessions are queryable and renderable in the htmx UI (and via /api/eval). The store must stay the most inspectable layer.

3 borge/single-image.borg

pricklypear-single-image

Book chapter: the single-image process model. One unix binary, one Postgres, one deployment. Multi-user at the session/branch layer, not process isolation. This chapter is the authority for process topology; an earlier multi-process design (supervisor + authd + per-user unikernels) was retired.

[status: implemented]

single-image

One unix image process: model, topology, auth placement, deployment

[status: implemented]

thesis

What the system IS

[status: implemented]

Pricklypear is ONE OCaml unix binary – the image – that:

1. Serves htmx HTTP directly on a port (Httpun_eio + pure-html). This is the only user-facing surface. 2. Talks to Postgres via pure pgx over Eio.Net (Io_eio). Postgres is the durable object store; the image is ephemeral and rebuildable from the store plus the package seed (libs/*.pp -> system/main). 3. Reads its identity (branch, author) from process env at boot – no boot manifest, no external injection. 4. Optionally exposes a line-protocol REPL on a second port for operator access. The browser REPL (/repl) and HTTP eval (/api/eval) are the primary interactive surfaces.

Scope – what the system is NOT:

- Not a MirageOS unikernel. No Solo5 target in v1. ‘dune build‘ + restart is how the image changes. (Solo5 remains an optional later hardening spike – spikes/mirage_solo5/ – not the product path.) - Not multi-process. No supervisor, no authd sidecar, no fleet. The image is the only Pricklypear process. - Isolation between humans lives at the session and branch layer, not the process layer. There is no per-user image instance.

Rationale: one process cannot fail the ways a coordinated multi-process topology can – no port races on respawn, no stale route tables, no orphaned children, no cross-process identity handoff.

topology

The physical layout

[status: implemented]

OpenBSD host (build + runtime habitat):

+– Postgres (shared object store, SERIALIZABLE | defaults) | +– pricklypear image (ONE unix binary) | +– Httpun_eio on PP_HTTP_PORT (htmx UI, | | /api/eval, /repl, user routes) | +– optional line-protocol REPL on | | PP_REPL_PORT (operator only; Lwt_eio bridge) | +– Io_eio.Pg to Postgres (function_defs, | data_rows, branches, auth tables) | +– nginx (edge) +– TLS -> proxy_pass http://127.0.0.1:PP_HTTP_PORT

Flow for "user adds a function": 1. Open the browser (nginx front door). 2. /repl or the function editor: the define persists to function_defs and is registered live. 3. Routes serve it immediately.

auth

Where verify runs

[status: implemented]

Verify runs IN the image. Password and session verify happen in-process against the users, credentials, and auth_sessions tables; the /login cookie middleware guards the HTTP surface. No separate authd exists.

nginx basic-auth/htpasswd is an emergency edge gate only – it is NOT the user database.

Multi-user (many humans, sessions, personal garden branches) is a product layer above this process model; see auth.multi-user-product for the user stories.

runtime

Runtime effects: direct-style core, algebraic-effect rim, Eio floor

[status: implemented]

> *[verify] build: dune build && dune runtest; test: image/test/io_eio_test.ml; smoke: image serves /health and a CRUD roundtrip under PP_IO=eio; smoke: (with-transaction (lambda () (create ...))) commits; select-for-update inside body sees the lock, on the default backend*

Three layers – never collapse them (the two \"effects\"):

A. GUEST CAPABILITIES – what a Nopales expression may touch (pure / read-db / write-db / branch / publish / ai / html / txn). Static AST inference in lisp/lib/effect.ml; drives badges and gates. Spec: lisp-interpreter.effects. NOT this section. B. HOST CONTROL EFFECTS – how eval does I/O without monads. OCaml 5 Effect.perform of one effect: Prim_call : string * value list -> value Effect.t declared in lisp/lib/control.ml. Guest Nopales can never perform it; eval's prim dispatch is the only performer. C. I/O RUNTIME – who schedules sockets/DB/fibers. Lwt today; Eio is the floor we are moving to. The power company; chosen last, replaceable first.

This subsection is the book authority for layers B and C. The phase plan and runbook live in docs/runtime-effects-transition.md (H0 audit -> H1 direct-style core -> H2 Io port -> H3 backend swap); that doc is the runbook, this is the law.

LAYER B – HOST CONTROL EFFECTS (H1, SHIPPED):

- lisp/ is direct-style: Eval.eval returns value, no monadic types, no Lwt dependency. - Eval's prim dispatch performs Prim_call(name, args); prim bodies do NOT recurse into eval (guest lambdas needing DB access go through with-transaction's dynamic scope instead). - Pure tests install Control.run_sync with a sync prim table: service-free, no rim. - The image runs every eval under Control_rim.run (Effect.Deep.match_with): Prim_call looks up the registered prim fn, runs it, continues (or discontinues on raise). Pure lisp/ tests stay green with no services.

LAYER C – IO PORT + EIO FLOOR (SHIPPED):

- Process entry is always Eio_main + Httpun_eio accept loop. Domain SQL goes through Io.DB (io.mli) ? store_db.ml ? Io_eio.Pg (pure pgx over Eio.Net). scripts/check_io_rim.sh enforces the rim. - Store/crud/auth/session/agent_tools are direct-style: plain 'a returns, prim_fn = value list -> value, register_sync everywhere. DB calls block the calling fiber; a reentrant per-connection mutex serializes whole transactions across concurrent fibers. - HTTP page work is Fiber.fork'd off the connection read fiber so body reads (schedule_read) cannot deadlock against Promise.await. - Prim registration peeled into prims_request / prims_net / prims_media / prims_graph / prims_db; session.ml keeps t, rehydrate, checkout, eval, seed_stdlib, and register_session_control_prims. - Residual Lwt is rim-only: optional TCP REPL and curl-backed llm/http-get/sleep via Lwt_eio bridges. A later pass can replace those without touching domain code.

DYNAMIC TRANSACTION SCOPE (preserved):

- Store_db.with_dynamic_transaction binds current_tx around a thunk; crud execute paths prefer current_tx over the pool conn, so all prims in a (with-transaction (lambda () ...)) body share one SERIALIZABLE tx and select-for-update locks persist across prims in the body. Nested with-transaction fails (no

silent flattening). Binding is per-fiber under the conn mutex, never ambient-global.

RIM LINT:

- scripts/check_io_rim.sh stays green: only store_db / io_eio (and legacy io_lwt name) call pgx execute.

HARD INVARIANTS (every horizon, restated):

1. Composition: (define u (get ...)) then (str u) yields a plain value, never a promise. 2. (with-transaction ...) dynamic scope as above. 3. Budget/cancel: one bad eval cannot wedge the image (budget ticks at each eval step AND at each rim prim dispatch). 4. Pure lisp/ tests stay service-free; image smokes stay green on the default backend. 5. Capability inference (layer A) unchanged; guest Nopales never gains Effect.perform.

net-prims

Network primitives: tcp-connect + stream read/write/close over Eio.Net (egress v1)

[status: implemented]

> – *agent note:* 2026-08-05: implemented v1 egress net prims (tcp-connect, stream-write, stream-read, stream-close, stream-list) in image/lib/net_prims.ml using OCaml Unix blocking sockets (not Eio.Net – Eio switches are run-scoped with no standalone make, so persistent handles need a service-manager switch; filed BORGE-1785968883). Session stores a net_streams table of Unix.file_descr. Tested on local dev: full HTTP round-trip to example.com works (connect -> write -> read -> close). 160 dune tests green. Ingress/tcp-listen/TLS deferred to v2 (BORGE-1785967056).
>
> *[verify] build: dune build; test: dune runtest – net prims (mock/local); test: (tcp-connect host port) returns a stream handle; test: (stream-write handle bytes) writes; (stream-read handle n) reads up to n bytes; test: (stream-close handle) closes the socket*

v1 SCOPE: EGRESS ONLY. Lisp code can open outbound TCP connections and read/write byte streams. This makes MQTT/IRC/SMTP/WebSocket client libraries possible as pure Nopales, without a kernel sidecar. Ingress (tcp-listen, spawn-service, long-lived accept-loop fibers) is deferred to v2 – it needs a service-manager switch outside the per-request scope and lifecycle introspection (BORGE-1785967056).

PRIMS (v1): (tcp-connect host port) -> stream-handle | error Opens an outbound TCP connection to host:port using Eio.Net.connect on a switch scoped to the handle's lifetime. Returns an opaque VStr handle id (a UUID) registered in a session-local stream table. (stream-write handle bytes) -> n-written | error Writes the byte string to the stream (Eio.Flow.write). (stream-read handle max-bytes) -> bytes-string | error Reads up to max-bytes bytes (Eio.Flow.single_read into a Cstruct, returns as VStr). One budget tick per read. (stream-close handle) -> ok Closes the socket and removes the handle from the session stream table. (stream-list) -> list of open handle ids Introspection for debugging.

CAPABILITY GATING: tcp-connect requires the Net capability (new badge; see effect.ml). Public routes may not call net prims. Per-user/branch quota on open streams (default 16) to prevent resource exhaustion. Anonymous sessions denied.

LIFECYCLE: Stream handles live in a session-local table. The switch is scoped to the eval call (so an abandoned stream closes when the eval returns) OR to the session (for multi-call stream use). v1: per-eval-call switch (simplest, safest). The handle id is a UUID string; the table maps id -> socket.

STEP-BUDGET INTERACTION: Each stream-read is one budget tick (like extract-links). stream-write is one tick. A blocked read on a silent peer

could hang an eval call; mitigate with a per-read timeout (default 30s) returning an error string, not a hang.

NON-GOALS (v1): - tcp-listen / ingress (v2, needs service-manager). - spawn-service / long-lived fibers (v2). - TLS wrap (v2; eio-tls not in poohstack yet). - UDP. - DNS resolution beyond getaddrinfo (Eio.Net handles it).

deployment

One binary, one rc.d service, one restart

[status: implemented]

rc.d service 'pricklypear' (scripts/rc.d/pricklypear): start -> /usr/local/libexec/pricklypear/current/bin/image with env from /etc/pricklypear/pricklypear.env stop -> kill the single PID restart -> stop + start (one process, one port, clean shutdown)

Release promotion (git push to prod): 1. build the release (lisp + common + image) 2. extract to /usr/local/libexec/pricklypear/releases/<id> 3. swap the 'current' symlink 4. rcctl restart pricklypear

(Full hook/runbook detail: docs/openbsd-prod-branch-deploy.md.)

Changing a primitive: edit image/lib, push, the promote step rebuilds and restarts. Changing an app: define or route on a branch in the live image – no deploy at all.

4 borge/object-model.borg

pricklypear-object-model

Pricklypear book chapter: object-model
[status: partial]

Typed records in Postgres, schema declared in Nopales, SQL-via-primitives, no ORM
[status: partial]

> *[verify] build: dune build @all; test: image/test/primitives_test.ml 48 alcotest cases incl. CRUD + deftype + dict + render-html; smoke: CRUD + deftype + dict + render-html exercised end to end*

An "object" is a typed record with an id, a set of named typed fields, stored in Postgres. There are NO methods on objects. Methods are functions in the store that take an object id as argument. This is functions + data, not OOP, matching the poohstack shape.

Types are DECLARED IN LISP, not in SQL migrations:

(deftype event (fields (title :string) (start :timestamptz) (end :timestamptz) (owner :ref user) (attendees :array (ref user))))

The declaration lives in a code-store table (type_defs, branched like code). It registers the type – it does NOT emit DDL. All data rows of all types live in the shared data_rows table keyed by (type_name, id), fields packed as jsonb.

The type is itself inspectable data: the htmx UI can render "list all types, show fields, browse instances" nearly free. This is the Smalltalk-image browser feeling, achieved via a metamodel rather than via live mutable objects.

CRUD primitives (real OCaml, typed at boundary): (create 'event {...}) -> row insert (get 'event id) -> row fetch (update 'event id {...}) -> row update (delete 'event id) -> row delete (rows 'event) -> all rows of a type (find-row / find-rows / find-text ...) -> lookup (select-for-update ...) -> explicit row lock

References are first-class values: a :ref user field holds an id + type tag. Dereferencing is explicit: (get 'user (event-owner ev)).

The Nopales still has plain values (int, string, bool, lambda, list, ref) for logic that doesn't touch the DB. Pure functions for "does this event conflict?" take event values, return bool, no DB. The DB and Nopales have a clean seam.

NO ORM. The primitive layer reads and writes the shared data_rows table with plain SQL and parses results into typed Nopales values.

type-system

Field types and reference semantics
[status: partial]

Field types (initial cut, grow as needed): :string text :int int8 :bool bool :timestamptz timestamptz :ref <type> id of a data_rows row of <type> :array <type> <type>[] (homogeneous) :json jsonb (schemaless escape hatch)

Field values are stored in the data_rows.fields jsonb – there are no per-type tables (see storage.schema).

A (ref user) value is a tagged id: the value carries its target type so the interpreter can verify derefs at call time. Dereferencing returns the full record or a stub-ref that lazy-loads on field access (decision deferred; start eager).

Cycles in the type graph are allowed (user has :ref calendar; calendar has :ref user) because refs hold ids, not nested values.

No inheritance, no subtyping. Composition via references, not via type hierarchies. This matches the poohstack (relational, no ORM, no inheritance) and avoids the Postgres INHERITS trap (see storage.no-inheritance).

– *agent note:* one-tree P6: boundary validation + type-fields/node-path/backlinks prims land the declared-field half; :ref as path + full field-type lattice still open.

– *agent note:* 2026-08-02 confirm still partial: deftype+type-fields+Tree_store.validate_fields exist; typed :ref/:array lattice and setuid-style ref deref incomplete.

5 borge/one-tree.borg

pricklypear-one-tree

Pricklypear book chapter: one-tree – ONE BIG TREE as the storage substrate, typed nodes for data modelling
[status: partial]

– *agent note:* 2026-08-02 status reconcile: tree-model/typed-nodes/projections/non-goals implemented; branching-interaction+migration-plan still partial (shared /data A, full tree-diff merge, phase-3 retire tables).

one-tree

One tree is the storage truth. Tables become projections. Nodes carry types.
[status: partial]

[verify] build: dune build @all; test: image/test/tree_store_test.ml – 7 alcotest cases; smoke: ksh scripts/verify_one_tree.sh (tree_verify + eval smoke on :18080)

========== THE IDEA ==========
Everything in Pricklypear is stored in ONE BIG TREE. The tree is the source of truth. Code, types, routes, data, docs – all of it lives as nodes in one rooted, typed, path-addressed tree. Nopales code IS tree content: a function's AST is a subtree.

Today the image already simulates this tree on top of relational tables: branches/function_defs/type_defs/ view_bindings reconstruct hierarchy via branch_id columns, parent pointers, and recursive-CTE override walks. Merge and promote are tree-diff algorithms written in SQL. The relational layer is scaffolding around what is already a tree. This chapter removes the scaffolding.

This is the Smalltalk/GemStone lineage Pricklypear comes from: the persistent thing is the object graph, and queries are programs over the graph. One unix image process serializes structural mutation, so the classic one-tree-store objection (concurrent writers) mostly evaporates – one writer, and a "transaction" is: evaluate, commit the new root.

WHAT CHANGES: - The tree is TRUTH. Rows are DERIVED. - Storage addressing is by PATH, not by (table, branch_id, name). - Merge/promote become honest three-way tree diffs instead of row-level branch inheritance. WHAT DOES NOT CHANGE: - The Nopales prim ABI. get/create/update/delete/ rows/list-bindings/describe/deftype keep their signatures. The prim/effect seam – the core performs I/O via Control.perform_prim (OCaml 5 effects; see runtime-effects-transition) and the rim handler answers through the Io.DB port – was built for exactly this swap. Nopales code and route handlers never see the difference. Lwt remains only as the v1 rim backend (Io_lwt); the direction is effects everywhere, Lwt is the replaceable power company, not the model. - Postgres remains the physical substrate (byte durability, backups, pg_dump). The tree is a Postgres-RESIDENT structure, not a new database. - additive-only migrations still govern whatever physical tables the tree store itself uses. - The effects direction (runtime-effects-transition): one-tree changes WHAT the rim reads/writes, not HOW the core talks to the rim. Core stays direct-style via Control.perform_prim; any Lwt still present is vestigial rim plumbing (Io_lwt), to be replaced (Eio or other) on the H3 schedule – it is NOT the model and should not grow.

tree-model

The tree: one root, typed nodes, path addressing
[status: implemented]

ONE TREE, ONE ROOT:

/ ??? sys ? ??? pkg/<package>/<name> function AST subtrees ? ??? type/<type> type declarations ? ??? route/<route> route ? handler bindings ??? user/<username>/... same shape per user ??? data ??? u.<user>.<type>/<id> per-user data nodes ??? shared.<type>/<id> shared/seed content (see branching-interaction)

BRANCHES ARE LENSES, NOT COPIES. A branch is a name ? subtree-root pointer into the one tree (system/main, <user>/personal, <user>/dev are views). Fork = record a new pointer. Override = pin a subtree. Unpinned names resolve through the lens to main. This replaces today's "recursive CTE up the parent chain" with pointer chasing in the structure the data actually has.

PHYSICAL FORM (v1, Postgres-resident): - Tree nodes serialized as JSONB (Nopales ASTs are already JSONB today – this formalizes it). - Path index: materialized path per node (ltree or text path column) so "give me all of /data/todo" and "give me subtree /sys/pkg/notes" are indexed lookups, not tree walks. - Per-subtree hashes (content-addressing later; detection + vault integrity now). A corrupt root must be detectable, and pp-sync snapshot must stay meaningful.

ADDRESSES ARE STABLE. A node address (/user/alice/pkg/notes/doc/get, /data/flash-card/<id>) is the durable name other nodes reference. Moves go through an explicit refile op so references can be rewritten (see notes links-and-roam refile, and structural-editing for the shared tree-op protocol this plugs into).

========== PINNED (P0) – concrete v1 decisions ==========

The tree is realized over TODAY's tables first; each existing row maps to exactly ONE typed node. Paths are DERIVED from row identity (no behavior change):

PATH GRAMMAR (branch-aware code/types/routes/packages): fn b.<branch_id>.fn.<name> type b.<branch_id>.type.<name> route b.<branch_id>.route.<route> pkg b.<branch_id>.pkg.<name> (* agent note (|pkg added 2026-08-02 for lisp-interpreter.package-surface Phase 1 – package registry rows (enabled bit + export list) are branch-lensed like fn/type/route so per-user enable/disable inherits parent->child via the same override walk.|) *) DATA (USER-OWNED – see branching-interaction /data DECISION, revised 2026-08-02): data is owned by USERS, not branches. A datum's owner is the session user at create time: datum data.u.<user>.<type_name>.<id> shared data.shared.<type_name>.<id> No branch id in the path, no lens walk, no inheritance – a session sees exactly its own data.u.<user>.* plus data.shared.*. Branches stay purely a CODE concept (branching.borg's "branches are for code, not data" stands). Fork/merge/promote never touch datum nodes, so there are no data carve-outs in those semantics. (Legacy pre-revision paths were data.<type_name>.<id>, one shared pile – see the migration note in branching-interaction.) NOTES HIERARCHY (notes.storage – NOT kind=datum): folder data.note.u.<user>.<folder-segs?> note data.note.u.<user>.?.<slug> heading data.note.u.<user>.?.<slug>.h.<nid> Reverse-mirror ignores non-datum kinds; hierarchical notes must never be written as kind=datum. The notes garden keyed data by USER (u.<user>) from the start – user-owned datum placement generalizes that exact key to every flat CRUD type (todo, flash-card, ?). META (system, branch-free): user/cred/session/media meta.<kind>.<id>

Branch inheritance is NOT baked into the path. The override-walk (recursive CTE up branches.parent_id, depth ASC, first-occurrence dedup) is REPLACED at read time by: try path under self, then parent, up the chain – first hit wins. Rehydrate loads ancestors-first (depth DESC) so child pins override by re-define. Same semantics, honest representation.

NODE ENVELOPE (jsonb payload per node): { v: 1, kind: fn|type|route|datum|user|cred|session|media, path: text (materialized), type: text (datum: type_name; else node class),

body: json (fn AST / type fields / route {handler,visibility} / datum fields), author: text, doc: text|null (fn only), hash: hex (sha256 over canonical body) } Hash covers ONLY canonical body (not path/author) so content-corruption is detectable independent of placement. Per-subtree root hashes compose from leaf hashes (content-addressing later).

TIMESTAMPS: created_at and updated_at are ROW COLUMNS on tree_nodes (see physical layout), NOT duplicated into the payload jsonb. They are the source of truth for when a node was inserted and last rewritten; the upsert ON CONFLICT path advances updated_at = now() and leaves created_at untouched. The tree-prim JSON SURFACE (node_to_json – what tree/get, tree/list, tree/get-uuid, tree/find-by, tree/list-kind return) MUST include created_at and updated_at alongside the envelope fields, read from the row columns. A node returned by any tree prim without these two keys is a defect.

INDEXED READ PRIMS (tree-model PINNED, BORGE-1785516998): two dedicated read prims drive the path index so subtree access is a ltree GiST index scan, never a full tree walk, regardless of how large a subtree grows (projections.budget-scale: an O(subtree) walk does not scale as a subtree grows): (tree/children-of path [limit]) -> DIRECT CHILD nodes of path via the materialized path index (the same nlevel(path)=nlevel(prefix)+1 selection list_children uses, which also pulls folder/note grandchildren under the hierarchy at depth+2). Budget-safe; returns node JSON list. (tree/subtree path [limit]) -> CAPPED subtree payload of nodes under path via the path index (all descendants), ordered by path (depth-first). [limit] caps the result (default matches the existing list_subtree cap); pass an explicit [limit] for a tighter bound. Returns node JSON list. Both are READ-ONLY, kind-agnostic (they return datum and hierarchical nodes alike), and share the SAME node JSON surface (node_to_json) as tree/get + tree/list, so created_at/updated_at are present by construction. tree/list with depth=1 remains equivalent to tree/children-of, and tree/list without depth to tree/subtree without limit; these dedicated prims exist to make the indexed-read intent explicit and to give subtree a caller-supplied cap.

LENS-AWARE READ PRIMS (tree-read-prims, BORGE-1785516993): the plain prims above address nodes by their FULL materialized path. The store-tree ROOTS the tree-browser v2 needs (/sys/... + branch lenses) require resolving logical names through the branch OVERRIDE CHAIN – a session on <user>/personal must see the EFFECTIVE definition for tree_nodes, same closest-ancestor-wins rule function_defs use. These take a RELATIVE logical suffix ("fn.<name>", "type.<name>", "route.<route>", "pkg.<name>") and resolve it across the session's lens chain (self -> parent -> ... -> system/main): (tree/lens-get suffix) -> the closest node across the chain (node JSON) or empty when none has it. (tree/lens-children suffix [limit]) -> DIRECT children of the effective node's subtree under the branch that owns it. (tree/lens-subtree suffix [limit]) -> capped descendants of the effective node's subtree. The suffix NAME segment is label-encoded (fn_path/type_path/ route_path/pkg_path semantics); the branch id is implicit from the session chain. Same node_to_json surface (created_at/ updated_at present). Anonymous sessions resolve their effective chain via the anon/default lens.

PHYSICAL LAYOUT (migration 009_tree.sql; additive): tree_nodes(id uuid PK DEFAULT gen_random_uuid(), path ltree NOT NULL UNIQUE, kind text NOT NULL, type_name text, – datum only payload jsonb NOT NULL, hash text NOT NULL, author text NOT NULL, created_at timestamptz DEFAULT now(), updated_at timestamptz DEFAULT now()) – GIN on payload; btree (kind,type_name); – ltree GiST on path for subtree queries. tree_branches(– lens registry branch_id uuid PK REFERENCES branches(id), root_path ltree NOT NULL, – b.<branch_id> parent_id uuid, – kept in v1 head_hash text) – subtree root hash branches table stays in v1 (branch_id uuid + parent chain); tree_branches adds lens pointer + head hash. /meta and /data are NOT under any b.<id> – they sit outside the branch lenses entirely. /meta is system bookkeeping. /data is partitioned BY USER, not by

branch: data.u.<user>.* is that user's rows, data.shared.* is shared/seed content. A session sees exactly its own u.<user> subtree plus shared – visibility is a path-prefix confinement, not a lens walk, and there is no inheritance. See branching-interaction for the full rule.

LENS = branch_id + its parent chain. A read resolves a logical name by walking the chain's path prefixes. This is the v1 lens; true content-addressed pointer moves (fork = new pointer, promote = move main head) arrive in P5 once the tree is truth.

NEXT FREE MIGRATION: 009 (001..008 exist). tree_store module: image/lib/tree_store.ml.

SINGLE WRITER: the one image process serializes structural mutation. A commit is "evaluate, publish new root." No lock manager, no merge-on-write races inside a commit. Concurrency control moves up to with-transaction over tree subtrees.

> *[verify] build: dune build @all; smoke: addressing: resolve /data/todo/<id> and /sys/pkg/notes/<fn> to nodes via path index; smoke: subtree hash detects corruption of a stored node*

typed-nodes

Every node has a type; types are the data-modelling layer

[status: implemented]

Every node in the tree carries a TYPE. This realizes object-model.type-system (planned) as the tree's data-modelling layer – types are how the tree is structured, not an annotation on rows.

KINDS OF TYPED NODE: - CODE nodes – type is the AST shape (defn, deftype, route). A function IS a subtree whose root is a 'defn' node. - DATA nodes – a product type, declared in Nopales: (deftype note (fields (title :string) (body :string) (tags :array :string))) (deftype flash-card (fields (front :string) (back :string) (due :timestamptz) (deck :ref flash-deck))) (deftype flash-deck (fields (title :string) ...)) Notes, flash cards, todos, calendar events, workouts – every product's data model is a set of typed node shapes under /data/<type>/. - SCHEMA nodes – the type declarations themselves live in the tree under /sys/type/, so a type is inspectable data like everything else (the Smalltalk metamodel-browser feeling).

FIELD TYPES: as object-model.type-system – :string :int :bool :timestamptz :json :ref <type> ? a PATH reference to a typed node :array <type> ? homogeneous In one-tree, a :ref is literally a tree path, not an opaque id – dereferencing is a path lookup, and the tree can answer "what points at this node" (backlinks) from the path index. This is the query roam wants.

VALIDATION AT THE BOUNDARY: the prim layer checks a node's fields against its type declaration on create/update. Nopales stays dynamically typed internally (per roerick: the product surface tolerates jank); the tree boundary is where shapes are enforced. The OCaml outer shell is where correctness is proven (formal-verification).

NO INHERITANCE, NO SUBTYPING – composition via :ref, exactly as object-model.type-system already rules and storage.no-inheritance already argues. One-tree does not re-open that decision; typed nodes are flat shapes composed by reference.

RELATION TO TODAY: data_rows rows ARE these typed data nodes, packed as jsonb; type_defs rows ARE the schema nodes. One-tree does not invent new data semantics – it gives the existing semantics their natural shape and makes types load-bearing (validation, backlinks, structural ops) instead of documentary.

> *[verify] build: dune build @all; smoke: create a flash-card node missing a required field ? clean rejection naming the field; smoke: :ref deref resolves via path; backlink query lists nodes referencing a given node*

tree-datum-prims

Tree prims are a complete data API: tree/upsert, tree/move, tree/delete operate on datum nodes, not only hierarchical kinds

[status: implemented]

DATUM NODES ARE FIRST-CLASS TREE NODES (tree-model, typed-nodes). The tree prim family must therefore operate on them directly – not only on hierarchical kinds (folder|note|heading). Today tree/upsert rejects any kind outside the hierarchical set, so datum writes can only reach the tree through the create/update CRUD prims (which generate the path and id internally via tree_datum_path). That makes the tree prims an INCOMPLETE data API: a product cannot move, reorder, or re-parent a datum node with a tree action. This subsection closes that gap. Kanban (notes.borg) is the first product consumer; it moves cards between columns by tree/upsert of the card's datum node with a new status field, and reorders within a column by tree/upsert with a new position.

tree/UPSERT with kind="datum": - Accepts a caller-supplied datum path of the form data.u.<user>.<type_name>.<id> or data.shared.<type_name>.<id>. <id> is a uuid. - When the path's id label is a placeholder (empty or a sentinel), generate a fresh uuid and build the path the way insert_datum does, so a caller can create a new datum node by path without pre-allocating an id. - Runs the SAME typed-boundary validation as the create/update CRUD prims (check_type_fields over body_json against the declared type_name): a missing required field is a clean rejection naming the field. Undeclared types accept free-form JSON. - Writes the tree_node with kind=datum, type_name set, the standard envelope payload, and a body hash; ON CONFLICT (path) DO UPDATE the body (and hash, author, updated_at) so the same prim upserts and updates. - The reverse mirror (migration 009 forward trigger) keeps the data_rows projection in lockstep, so (get 't id), (rows 't), and the /data browser see the node identically to one written via create.

tree/MOVE on a datum path re-homes the datum: rewrites the path and payload.path of the node (and, for a recursive move, its subtree), and the reverse mirror syncs the projection. This is the re-parent / re-board operation. Moving a datum to a path under a different <type_name> is a type change and MUST re-run typed-boundary validation against the new type.

tree/DELETE on a datum path removes the node (and optionally its subtree when recursive); the reverse mirror removes the projection row. Already kind-agnostic in code – locked here as a datum-capable prim, not a hierarchical-only one.

tree/GET, tree/LIST, tree/FIND-BY, tree/LIST-KIND are kind-agnostic readers and already return datum nodes; this subsection locks that as the contract (a datum node is readable by path, by prefix, by body field, and by kind just like any other node).

RELATION TO THE CRUD PRIMS: create/update/delete remain valid – they are the id-generating, session-user-path-injecting convenience surface for the common "insert a new row of type T" case. tree/upsert is the PATH-EXPLICIT variant for when the caller owns the path: moves, reorders, re-parents, and products that model their data as a shaped tree rather than a flat table. The two surfaces write the same tree_nodes rows through the same mirror; they are interchangeable views of one store.

COMPOSITION SURFACE (no new prims needed for the common data operations): - FIELD UPDATE on a datum (change one field, e.g. a card's status or position): tree/get the node, dict-get its body, dict-set* the changed field(s), tree/upsert the new body at the same path. This is the same read-modify-write the todo package already uses against create/update. - ATOMIC MULTI-NODE OP (e.g. reordering N cards in a column after a drag): wrap the field updates in with-transaction so the reorder is all-or-nothing. - RE-PARENT / MOVE TO NEW BOARD: tree/move to change the path, or tree/upsert with a changed parent-id field when the product models parenthood

as a field rather than a path (the flat todo model does the latter – list_id is a field, not a path segment). The path helpers node-path, type-fields, and backlinks are the datum path-construction and reference-query surface; they are already kind-agnostic and need no change.

> *[verify] build: dune build @all; smoke: tree/upsert a datum node of a declared type with all required fields ? node appears at the given path; (get 't id) returns the same fields; smoke: tree/upsert a datum node missing a required field ? clean rejection naming the field, identical to create; smoke: tree/upsert an existing datum path with a changed field ? body updates in place; (rows 't) reflects the new value; smoke: tree/move a datum node to a new path ? (get 't id) at the new path returns it; old path is gone; projection in sync; smoke: tree/move a datum to a path under a DIFFERENT type_name ? re-runs typed-boundary validation against the new type; a missing required field rejects cleanly naming the field, the node stays put; smoke: tree/delete a datum path ? node and projection row both removed; smoke: tree/get, tree/list, tree/find-by, tree/list-kind all return datum nodes, not only hierarchical kinds; smoke: tree/get of any node returns JSON with created_at and updated_at keys; created_at is stable across an upsert rewrite, updated_at advances*

tree-read-prims

Explicit read prims over the one tree: tree/children-of for one level, tree/subtree for a capped all-descendants payload

[status: implemented]

Convenience read prims that give the materialized-path index a first-class name, instead of folding directory reads into tree/list's depth argument. Both are kind-agnostic readers over tree_nodes and share the tree-get/list JSON surface (node_to_json, including the created_at/updated_at row columns). Both are index-driven – never a full tree walk (see the CHILDREN-BY-LEVEL invariant in projections).

(tree/children-of path [limit]) -> VList of node JSON Direct children of [path], expressed as a LEVEL predicate (nlevel = nlevel(path)+1, with the outline covering at +2 under the literal label h so note outline roots are included), never a correlated NOT EXISTS anti-join. Backed by Tree_store.list_children. Semantically identical to (tree/list path 1); the explicit name documents the caller's intent and decouples it from the depth-arg convention. Default limit 50000.

(tree/subtree path [limit]) -> VList of node JSON All descendants under [path] (path <@ prefix), capped at [limit] rows (default 50000) so a huge subtree degrades to a bounded payload rather than a full walk. Backed by Tree_store.list_subtree. Semantically identical to (tree/list path) with the depth argument absent; the explicit name signals the caller wants a bounded snapshot, not a level read.

LENS-AWARE READ PRIMS (BORGE-1785516993): tree/lens-get, tree/lens-children, tree/lens-subtree resolve a RELATIVE logical suffix ("fn.<name>", "type.<name>", "route.<route>", "pkg.<name>") across the session's branch lens chain – self -> parent -> ... -> system/main, closest-ancestor-wins, the same override rule function_defs use. This is what the tree-browser v2 store-tree roots (/sys, branch lenses) need: a session on <user>/personal sees the EFFECTIVE override for tree_nodes, not just its own branch. The suffix name segment is label-encoded (fn_path/type_path/route_path/pkg_path semantics); the branch id is implicit from the chain. Backed by Tree_store.lens_get_in_chain / lens_children_in_chain / lens_subtree_in_chain over Store.branch_chain.

Anonymous (unauthenticated) reads resolve against system/main and are permitted for both prims; the nodes returned are confined to what the requesting identity's path prefix grants (data.u.<user> / shared).

> *[verify] build: dune build @all; smoke: (tree/children-of P) returns exactly the direct children of P (level predicate), including outline roots*

under P.h; smoke: (tree/subtree P) returns all descendants under P, bounded by the limit arg; smoke: both prims return node JSON including created_at and updated_at keys; smoke: tree/lens-get resolves a suffix across the branch chain with closest-wins (child override shadows parent; main effective on child); smoke: tree/lens-children/subtree read under the effective branch owning the resolved node

sibling-order

Children have a user-controlled order; the tree answers next/prev/first/last

[status: implemented]

THE GAP. ltree paths encode hierarchy, never order. Today children come back in path::text ASC (or created_at) order – an accident of the index, not a modelled fact. Every consequence of that is visible downstream: notes cannot do per-node move-up/move-down (its per-node store is "flat" partly because outline order only exists in the outline blob), no package can ask next/prev-sibling, and outline- style structures keep a second source of truth (the blob) just to carry sequence.

DESIGN. A nullable rank TEXT column on tree_nodes (fractional-indexing string, Figma/Linear style: "a0", "a1", "a1V", ...).

- NOT fractional path labels. The path is a materialized path: changing a label rewrites the subtree. Rank must be mutable without touching identity, so it lives in a column, not the path. The path is WHERE a node is; the rank is WHAT SLOT it is in. - NULL rank means unordered: ORDER BY rank NULLS LAST, path::text ASC. Existing rows need no backfill; ordering is opt-in per sibling set. - Ordering is a property of the node, so it is owned by the branch that owns the node under lens rules, and rank changes are ordinary writes: versioned, diffable, undoable (tree-time carries them for free).

PRIMS.

(tree/reorder path rank) set rank directly (tree/move-before path anchor) place before sibling anchor (tree/move-after path anchor) place after sibling anchor (tree/siblings path) ordered children of parent (tree/next path) (tree/prev path) adjacent ranked sibling (tree/insert-child parent kind type body [:after anchor])

tree/children-of and tree/subtree gain the ranked ORDER BY (rank NULLS LAST, path ASC); no signature change. Rank allocation is mid-point between neighbours, rebalance on exhaustion – a write-path detail, not visible in the ABI.

UNGATES. Per-node reorder for notes (killing the last reason for outline-as-blob), the notes/node-op move-up/move-down exclusion, and any future package with sequenced content (outline, playlist, pipeline stages) gets ordering from the tree instead of a private mechanism.

[verify] smoke: insert three children, move third before first: children-of returns new order; smoke: unranked siblings sort after ranked, path-ordered among themselves; smoke: reorder is versioned: gen-read at old gen shows old order; undo restores; smoke: child-lens override of a node owns its rank; parent rank unchanged

tree-path-prims

Kernel path algebra: one canonical set, replacing per-package string hacks

[status: implemented]

THE GAP. Path manipulation is re-implemented in Nopales by every package that touches the tree: notes/tree/parent-of, notes/tree/butlast, notes/tree/split-folder, notes/tree/join-slash, todo/tree/prefix, todo/tree/tail, tree/breadcrumb-parts. Path semantics (label encoding, segment splitting) belong in the kernel next to the ltree type they describe.

PRIMS (pure – no DB, no auth; label semantics identical to tree/path-label):

(tree/parent path) parent path or nil at root (tree/leaf path) final label (tree/segments path) VList of labels (tree/child path label) append (encodes label) (tree/ancestors path) every strict prefix, root-first

These compose with the existing read/lens prims – e.g. (tree/lens-children (tree/parent p)) is sibling navigation. They are pure string operations over the ltree textual form; invalid paths raise rather than guess.

DEPRECATION. notes/tree/parent-of &co become thin aliases to the kernel prims, then are removed in a later pass. New packages must not grow private path algebra.

NON-GOAL. Glob/pattern matching over paths (ltree ~ queries) stays admin/SQL-side for v1; the Nopales surface is constructor/accessor algebra only.

> *[verify] smoke: round-trip: (tree/child (tree/parent p) (tree/leaf p)) = p for data/b paths; smoke: label-encoding edge cases (dashes, dots, uuid labels) match tree/path-label; smoke: notes/tree/parent-of and kernel tree/parent agree on the notes corpus*

tree-edges

Links between nodes are first-class typed nodes – the graph is nodes AND edges

[status: partial]

MOTIVATION. typed-nodes already declares :ref fields as literal path references and promises the tree answers "what points at this node"; the one tree is an object graph (GemStone/Smalltalk lineage) and a graph is nodes AND edges. Today only one direction exists, and only as brute force: (backlinks needle) seq-scans every datum body for exact string equality. No out-links, no link kinds, no integrity, and the scan does not scale.

THE WEIRD PART (per roerick): a link IS a typed node. Not a wrapper type inside bodies, not a side table – an edge is a node of kind link under its source:

<source-path>.lnk.<id> kind=link, body { to, kind, label? }

Being a node, an edge inherits the whole tree stack for free: typed-boundary validation, versioning and time travel (gen-read/gen-diff/undo cover edges), authorship, branch ownership, and lens visibility.

PATH PLACEMENT. Edges are children of their SOURCE – links are content OF a node: a roam note links outward; a flash-card's deck ref is part of the card. Consequences, all intentional: - out-links is a children-by-level index read (kind filter), never a scan. - tree/move of the source carries its edges; tree/delete of the source removes them. Outgoing references die with their owner; incoming references survive at the target as dangles. - "from" is positional (the parent path), never duplicated in the body; bodies hold only to/kind/label.

DANGLING BY DESIGN. The tree is branched and lensed (branching-interaction): an edge on <user>/personal can point at a system/main node another branch later deletes or overrides. Hard foreign-key integrity would make deletion and global refactor impossible across lenses and contradicts fork freedom. So: to is branch-qualified path TEXT; resolution is a READ-TIME act against the reader's lens (effective node, closest-wins). An unresolved edge is DANGLING DATA – rendered as such, repairable, never an error state and never a write blocker. GemStone could enforce pointers because there was one object space; the lenses are deliberately many.

:ref UNIFICATION. Declared :ref fields (typed-nodes) and edge nodes are two spellings of one relation. At typed- boundary validation time a datum's :ref fields are materialized as edge nodes under the datum (edge kind from the field name), refreshed on update/delete. Free-form bodies may still contain path-valued strings – those are HINTS tooling may promote, never truth. One relation serves every graph query; the body field stays the human-writeable spelling.

PRIMS.

(link from-path to-path [kind [label]]) create edge node (from must resolve in the session lens; to is stored as given – may dangle) (unlink edge-path) tombstone the edge (out-links path) VList of edge JSON with resolution status (resolved target summary or a dangling marker) (backlinks needle [limit]) same signature; backed by edges (to = needle) UNION legacy body-string matches – the legacy half is DEPRECATED and logged

INTEGRITY AS WARN, NOT FORBID. tree/delete and tree/move report the incoming-edge count for their target; UI faces warn on non-zero. tree/move of a TARGET leaves inbound edges dangling (a repair/report surface is v2, non-goal).

> – *agent note:* 2026-08-28 make pass (tree-traversal branch): edges + prims implemented and smoked (link/unlink/out-links/backlinks, dangle-by-design, warn-not-forbid inbound reporting on tree/delete + tree/move – both now return JSON {deleted|moved, inbound_edges}, versioned edges incl. undo of unlink). PARTIAL for one reason: :ref materialization is deferred (BORGE-1787972072) because type_defs.fields are bare NAMES today – no field types, no deftype surface for :ref; that is a slice of the type-system track, not of this subsection. The edge shape and read-time resolution are independent of typed-boundary validation; materialization later is purely additive.

> *[verify] smoke: link a->b: (out-links a) lists b resolved; (backlinks <b-path>) includes the edge path; smoke: tree/move of the target: the edge reports dangling on read; textual backlink still finds it (legacy half); smoke: tree/delete of a node with 2 inbound edges reports count 2 and succeeds (warn, not forbid); smoke: edge nodes are versioned: gen-diff shows edge add; undo of unlink restores the edge; smoke: datum with a declared :ref field gains a materialized edge node; update refreshes it; delete removes it*

tree-browser

Generic /tree face over tree_nodes: navigate any subtree on the session lens

[status: implemented]

THE GAP. There is a tree/browser-shaped package (tree/*) but it is a single-document outline viewer hardwired to scripture_concepts. There is no face over the store itself. If everything is one tree, the user should be able to stand at any node and walk.

SURFACE. /tree?path=P on the session branch lens, anonymous confined to public prefixes per tree-read-prims.

- Root defaults to the identity's garden root (tree/garden-root); ?path= focuses any node. - One level via tree/lens-children, lazy-expanded through htmx partials (the notes-ui-contract lazy-load pattern, CHILDREN-BY-LEVEL index form only). - Breadcrumb from tree/ancestors; kind/type filter; ranked order from sibling-order; as-of-gen view via tree-time (?gen=) with gen-diff highlighting against head. - Node detail pane: body JSON, created/updated, author, rank, out-links/backlinks (tree-edges), edit affordance per tree/upsert auth rules.

RELATIONSHIP TO EXISTING FACES. Complements, not replaces: /data (typed-row tables), /bindings (code), /sys (admin store-tree). The existing tree/* package is renamed/merged into it later; no route changes in v1 of this subsection.

BUDGET. Every level read is one index-driven query; no whole-subtree walk is ever the page path (projections invariant). Depth-limited like tree/subtree.

> *[verify] smoke: anonymous /tree shows public prefixes only; private paths are not listable; smoke: lazy expand of one level issues exactly one chil-*

dren query; smoke: session on <user>/personal sees effective lens overrides, not just its own branch; smoke: ?gen=<old> renders the subtree as of that generation

projections

SQL over the tree: relational rows are derived, not truth

[status: implemented]

The tree is truth, but ad-hoc relational query is how you SEE it. Postgres stored procedures / views / materialized projections DERIVE (type_name, id, fields) rows from the tree:

- /data browsing, /types, admin grep-queries - reporting, pp-sync export, debugging - the existing CRUD prim RESULT SHAPES (rows returns (id . fields) pairs) are served from a projection even once the store is a tree

DEPENDENCY DIRECTION FLIPS. Today rows are truth and the tree is reconstructed by CTE; after one-tree the tree is truth and rows are a cache. Projections are REBUILDABLE – drop and regenerate from the tree at any time. Nothing authoritative lives only in a projection.

OPTION, NOT GATE: the stored-procedure projection layer is how relational tooling keeps working during and after the cutover. Nopales product code keeps calling the same prims; only the prim layer's backing moves from tables to tree + projection.

INDEXING: projections and the path index are what make "all nodes of type X" and "subtree at P" fast. A full tree walk is never the query path for product or admin surfaces.

CHILDREN-BY-LEVEL, NOT ANTI-JOIN: "direct children of P" is expressed as a LEVEL predicate – path <@ P AND nlevel(path) = nlevel(P) + 1 – never as a correlated anti-join (NOT EXISTS over an intermediate node). nlevel equality is a constant-bound predicate the ltree GiST path index can drive, so the children lookup stays an index scan regardless of how many nodes share the prefix; the anti-join form cannot use the index for its inner <@ and so degrades to O(subtree^2) as a subtree grows. Every read endpoint that lists one level of the tree (tree/list depth 1, folder expansion, the /notes index) goes through this level form. (* agent note (|Design invariant recorded 2026-08-02 from live measurement at ~3000 notes under data.note.u.admin: the NOT EXISTS anti-join in Tree_store.list_children took ~4000ms to return 11 root children (blocking /notes at ~8.6s and surfacing as budget_exceeded on dabar) while the level predicate and tree/list-kind took single-digit ms; the 100k-step eval budget is left unchanged – it is a tripwire that exposed this DB-plan bug, not the bottleneck.|) *)

OUT OF SCOPE (v1): exposing raw SQL to Nopales product code. The projection layer serves the image and admin tooling; the Nopales surface stays prims.

[verify] build: dune build @all; smoke: rows 'todo' returns the same (id . fields) pairs backed by a projection over the tree; smoke: rebuild projection from tree; diff against pre-rebuild state: identical

branching-interaction

Branches as tree lenses; the /data question; merge as tree-diff

[status: implemented]

– *agent note:* 2026-08-02 /data DECISION revised to USER-OWNED data (resolves BORGE-1785693032): datum under data.u.<user>.* + data.shared.*, RLS floor keyed on user. An earlier branch-keyed draft (b.<branch>.data.*) was rejected as a leaky abstraction – encoded user ownership in a branch path, then needed fork/merge carve-outs. Three-way tree-diff merge / promote-as-pointer-move

still incomplete vs scaffolding promote. Code still on the old shared pile – spec leads code here.

– *agent note:* 2026-08-14 DATA-BRANCHING BOUNDARY (design discussion, with local-first): single-head, user-keyed data STANDS – but it is a current-shape decision, not a hard no forever. Split MECHANISM from CONCEPT: (1) MECHANISM is SHARED – the 3-way tree-diff merge (subtree/node hashes) is one generic tool for both code lenses AND local-first data sync; do not build two merge algorithms. (2) CONCEPT is NOT branchable – data has no user-facing branch concept (no checkout, no 'dev copy of your todos', no lens-walking data). A device lens snapshot (admin/laptop) is SYN/MERGE-BASE METADATA – a replication convenience – not a sibling world; data is SPATIAL (which copy of one datum), not TEMPORAL (which version of the world). Local-first sync gets its merge base from (branch, generation) snapshot pins + node hashes, NOT from making data semantically branchable. REOPEN TRIGGER (falsifies the boundary): a real feature where a USER forks their OWN data to experiment and later merges it back (e.g. clone my notes, rewrite offline over a week, reintegrate). If that use case becomes real, user-keyed flat data creaks and this boundary gets a plan-phase re-look – with the branch-keyed rejection above as the explicit prior to beat. Near-term evidence single-head is right: local-first's first payloads (transcript appends, memory LWW) are deliberately single-head.

– *agent note:* 2026-08-23 PLAN-PHASE PROPOSAL (versioned user-keyed data): reopen the data-branching boundary recorded above. The 2026-08-14 boundary split mechanism (shared 3-way tree-diff) from concept (data not branchable) and named a reopen trigger: a user forking their own data to experiment and reintegrate. The local-first lens model IS that use case – a lens materializes a user's data subtree, edits offline, syncs back via three-way merge – and the boundary's defense ("data is spatial, not temporal") is contradicted by local-first's own sync design ("the git protocol in miniature": base/ours/theirs is a versioning act over a store claimed unversioned). The defense does not hold under the machinery built on it.

WHY THE CARVE-OUTS EXPIRED. The 2026-08-02 rejection of branch-keyed data (b.<branch>.data.*) rested on two operational costs: (1) fork must not copy the DB, and (2) deploy must not wipe data. (1) expired when fork became an empty-lens parent pointer (one-tree P5, copy-on-fork) – there is no multi-row copy to carve out. (2) was always about seed/reseed scope, not data keying: user data is never seeded, so reseed touches it regardless of keying. The conceptual defense that remains ("branches are for code, not data") is an assertion the lens model violates – a lens is a branch and a lens holds data.

PROPOSAL: VERSIONED USER-KEYED DATA. Isolation and versioning are orthogonal (the 2026-08-02 revision's own insight, applied to one axis only). Keep the user segment for isolation; add an OPT-IN lens segment for versioning. Path grammar: data.u.<user>.<type>.<id> live, single-head (UNCHANGED default) data.shared.<type>.<id> shared/seed (unchanged) data.l.<lens>.<user>.<type>.<id> a forked data lens (opt-in version)

The default (data.u.<user>.*) stays branch-free and single-head: checkout does not hide your data (the property the user-key fix bought). A deliberate fork creates a data.l.<lens>.<user>.* subtree that can diverge and merge back. Abandon = drop the lens

> subtree. Merge = three-way tree-diff (lens -> trunk), the SAME algorithm code lenses use and local-first sync already runs – one mechanism, not two.
>
> NOT the rejected branch-keying. b.<branch>.data.* keyed data by CODE branch, so checkout hid your data and fork/merge (code operations) had to carve data out. data.l.<lens>.<user>.* is a DATA-NATIVE lens namespace, user-keyed for isolation, opt-in for versioning. Code fork/merge (over b.*) never touches data.l.* unless the user explicitly forks data. The carve-out becomes: fork never touches LIVE data (data.u.*); a data lens fork is a separate, explicit operation.
>
> NOTES RECONCILIATION. The notes garden (data.note.u.<user>.?) is the legacy shape (type-before-user, predates the 2026-08-02 generalization; confirmed live on prod 2026-08-23: (tree/garden-root) -> data.note.u.admin). It migrates to data.u.<user>.note.? as part of the make – type segment standardized, heading substructure (.<slug>.h.<nid>) preserved as the type's internal hierarchy. One migration to the final shape, not two. See notes.borg personal-garden.
>
> MAKE-PASS SCOPE (what flips when accepted): the DEFERRED stanza below (726-730: "data is not versioned at all"); the non-goal at local-first.borg ("NOT re-opening branch-versioning of data"); tree-time.borg's branch-free assumption for data.* paths (data.l.* lens paths carry a generation coordinate like code branches; data.u.* and data.shared.* stay tree-wide); the notes path-grammar migration. The sync landing policy (local-first.borg) gains a third case: data-lens merge (lens -> trunk) alongside code-merge (pointer move) and live-data-sync (in-place reconcile). Conflict-resolution policy is open either way; this proposal gives it a primitive to act on (the deliberate fork) instead of only accidental cross-device divergence.
>
> – *agent note:* 2026-08-23 MAKE: v0 implemented – migration 023 (data.l namespace + RLS + trigger guard), tree_store datum_path ~lens, crud fork_data/merge_data_lens/abandon_data_lens/list_data_lenses, prims fork-data/merge-data/abandon-data/list-data-lenses. The DEFERRED stanza below is flipped. v0 merge is LWW (last-write-wins per node); three-way tree-diff merge is v1. Notes path migration (data.note.u.<user> -> data.u.<user>.note) is a separate make task.

BRANCH = POINTER INTO THE ONE TREE. Fork records a new lens; override pins a subtree; promote moves main's pointer to the lens's subtree. This is a strict simplification of today's parent_id + branch_id-row model: the semantics are IDENTICAL, the representation is honest.

MERGE / PROMOTE = THREE-WAY TREE DIFF. With ASTs as subtrees, merge diffing is structural (per-node), and last_synced becomes a root-hash comparison. This realizes branching.ast-nodes (planned) and feeds branching.change-set and review-merge: a change set IS a tree diff.

THE /data DECISION (REVISED 2026-08-02 – resolves BORGE-1785693032). The original question was: data_rows has NO branch_id – shared data (branching.data). One-tree offered two placements: A. SHARED SUBTREE – /data/<type>/<id> lives outside any branch, lenses reference it. Closest to today's semantics; data never versioned. B. VERSIONED DATA – /data lives inside each lens, fork versions data too.

REVISION: the A-vs-B framing conflated two axes. The axis the rule was WRITTEN for is BRANCH VERSIONING (a fork must not copy or wipe the DB). The axis that was MISSING is USER ISOLATION (whose rows a session

can see). Placement A chose global sharing to answer the versioning question, and in doing so silently made every user's rows readable and writable by every other user (BORGE-1785693032).

The revision closes the isolation gap on the USER axis, directly, without borrowing branch semantics: USER-OWNED DATA – a datum is owned by the USER whose session created it, keyed by that user: per-user data.u.<user>.<type_name>.<id> shared data.shared.<type_name>.<id> A session sees exactly its own data.u.<user>.* subtree plus data.shared.*. There is NO branch id in the path, NO lens walk, and NO inheritance – visibility is a plain path-prefix confinement on the owning user. (An earlier draft of this revision keyed data by BRANCH – b.<branch_id>.data.* – and let lenses inherit a parent's data. That was a bad abstraction: it encoded a USER-ownership fact in a BRANCH path, then needed carve-outs because fork/ merge/promote must not copy, diff, or move data. User-keyed paths state the rule once, honestly.)

WHY NOT BRANCH-KEYED: branches are a CODE concept (branching.borg: "branches are for code, not data"). Scoping data by branch would import fork/ merge semantics that data explicitly does not have, and then require spec text explaining why those semantics don't apply. The notes garden – the one per-user data shape already in the tree – keys by USER (data.note.u.<user>.?), not branch. User-keyed data generalizes the pattern the codebase already chose.

WHAT THIS PRESERVES (the load-bearing rules): - FORK NEVER TOUCHES DATA. There is nothing to carve out: datum paths contain no branch id, so fork/merge/promote (operations over b.<id> code lenses) structurally cannot copy, diff, or move a datum. branching.borg's "data is never versioned by branch and never wiped by deploy" stands, now by construction rather than exception. - data.shared is the home of seed/shared content. - The Nopales prim ABI is unchanged: (create ?), (rows 't), (get 't id) keep signatures; the prim layer supplies the session's USER from Request_context and confines the query to data.u.<user> + data.shared.

WHAT THIS FIXES (the multi-user story): - (rows 'note) in alice's session returns alice's notes plus shared – NEVER bob's. - The /data browser shows the session's own + shared rows, not the global table. - Cross-user reads require an explicit copy/move into data.shared or a deliberate grants mechanism – the right kind of friction. - NO inheritance of main data: a fresh user sees only data.shared (which an app seeds explicitly if it wants starter content). Apps own their seeding; the platform does not silently clone main's data into a user's view.

RELATION TO NOTES: the notes garden (data.note.u.<user>.?) already keys data by USER. User-owned datum placement GENERALIZES that exact key to flat CRUD types; the notes hierarchy keeps its own path grammar (kind=folder/note/heading, not kind=datum) and is unaffected.

ENFORCEMENT FLOOR (RLS): because Nopales is user-programmable, prim code is the primary access control but not the only one – a missed WHERE clause is a cross-user read. Postgres row-level security on tree_nodes is the backstop, and it is SIMPLE because the key is the user: one policy restricts kind='datum' rows to paths under data.u.<current_user> or data.shared, keyed off SET LOCAL pp.user established per-transaction by Store.with_transaction. No branch-ownership lookup, no inheritance to express. RLS gives deny-by-default at the single point all reads funnel through; the prim layer's path-prefix confinement is the same rule stated in app code.

IMPLEMENTED (v0, 2026-08-23 make): opt-in data lens versioning via data.l.<lens>.<user>.<type>.<id>. A deliberate fork (fork-data) copies the user's live data.u.* subtree into data.l.<lens>.<user>.*; merge-data applies LWW (last-write- wins per node) back to live and consumes the lens (the mirror trigger enforces one-path-per-id); abandon-data drops the lens without merging. The default data.u.<user>.* stays single-head and branch-free. v1 ambition: three-way tree-diff merge (base/ours/theirs) instead of LWW, and

conflict surfacing. See the 2026-08-23 PLAN-PHASE proposal above.

TYPE_DECLS: today per-branch rows, table shape shared (branching.schema-authority). Under one-tree, schema nodes at /sys/type/ follow CODE branching rules (branchable, promoted), while /data instances are user-owned. Branch code reading user data against a newer/older type decl follows the existing additive-only tolerance rule.

COTENANT ISOLATION: lenses enforce multi-user.cotenant-isolation – a session is confined to its own data.u.<user> subtree plus data.shared for DATA, and to its branch lens for CODE. This upgrades the guarantee from session+branch scoping of CODE to session+USER scoping of CODE AND DATA, expressed as path confinement and floored by the RLS policy above.

> *[verify] build: dune build @all; smoke: fork = new lens; override on lens A invisible to lens B; promote moves main pointer; smoke: user-owned /data: a note created in alice's session is NOT visible in bob's session; both see data.shared; smoke: no inheritance: a fresh user's (rows 'note) returns only data.shared content, nothing cloned from another user; smoke: RLS floor: SET LOCAL pp.user=bob; direct SQL SELECT of data.u.alice.* returns zero rows*

migration-plan

Phased cutover: shadow tree ? flip reads ? projections derive ? retire tables
[status: partial]

> – *agent note:* 2026-08-02 confirm: 009_tree + mirrors + tree_store + verify_one_tree.sh (P0-P2 territory). Phase 3 retire scaffolding tables not done; PP_TREE_* knobs remain. Added Phase 2b (data user-scoping backfill keyed off author + RLS on user) per the /data revision.

NO BIG BANG. The prim ABI is stable throughout; each phase is reversible.

PHASE 0 – ADDRESSING SCHEME (pure design; this chapter). Freeze the path grammar (/sys/?, /user/?, /data/?), node envelope (type tag + payload + hash), and the lens model. No code.

PHASE 1 – SHADOW TREE. A writer mirrors function_defs/type_defs/view_bindings/data_rows into the one tree on every commit. Tables remain truth; the tree is a derived copy. Proves addressing, path indexing, hashing – fully reversible.

PHASE 2 – FLIP READS. The rim's store backend (Io.DB impl; Io_lwt today) serves reads from the tree behind the unchanged prim ABI; tables become the write-through fallback. Diff tree-read vs table-read in CI for a soak period.

PHASE 3 – TREE IS TRUTH, ROWS ARE PROJECTIONS. Writes commit to the tree; the relational shape becomes a stored-procedure/view projection for /data, /types, admin. Retire the scaffolding tables (via additive-only migration leaving them inert, per house rule – never DROP).

PHASE 2b – DATA USER-SCOPING (the /data revision; resolves BORGE-1785693032). Independent of the read-flip, one additive migration: - New datum path roots data.u.<user>.<type>.<id> (per-user) and data.shared.<type>.<id> (seed). - Backfill: every existing data.<type>.<id> node moves to data.u.<author>.<type>.<id>, keyed off the row's author column (today's pile is effectively admin-authored, so most land under data.u.admin; content meant as seed moves to data.shared explicitly). - tree_data_rows view rewritten as a user-confined projection: rows where path is under data.u.<current_user> or data.shared – no lens walk, no UNION over a parent chain. - CRUD prims pass the session USER from Request_context into the datum path (create) and the confinement (rows/get/update/delete/find-text). - RLS policy + SET LOCAL pp.user land in Store.with_transaction; cross-user access test added to verify_one_tree.sh. The old flat data_rows

relation survives one cycle as a compat projection, then goes inert per the additive-only rule.

MIGRATIONS AS TREE TRANSFORMS. Schema change stops being DDL and becomes Nopales-level migration FUNCTIONS over subtrees (more in-spirit; real work). Physical tables the tree store uses still change only via additive-only SQL migrations.

BLAST RADIUS: per-subtree hashes + pp-sync snapshot as the vault keep corruption detectable and recoverable; a corrupt subtree is rebuildable from snapshot.

DEPENDS ON / FEEDS: - object-model.type-system (planned) – realized here as typed-nodes. - branching.ast-nodes, change-set, review-merge – tree diff is their substrate. - structural-editing – one shared tree-op protocol over outlines AND the storage tree. - notes links-and-roam – backlinks come from :ref path references. - migrations.additive-only – physical-shape rule unchanged.

> *[verify] build: dune build @all; smoke: phase 1: every commit appears in shadow tree within the same transaction; smoke: phase 2 soak: zero diffs between tree-read and table-read over CI window; smoke: phase 3: drop-write to scaffolding tables; /data + /types served from projection*

non-goals

What one-tree is NOT

[status: implemented]

- NOT a new database. Postgres is A physical substrate (the server's); the tree is Postgres-resident JSONB server-side. A local lens may use another substrate (filesystem) per local-first.borg – the prim ABI is substrate-agnostic, and a lens is a materialized subtree, not a second store. The tree's truth is logical (paths + envelopes + hashes), not physical; Postgres is how the server holds it, not what it IS. - NOT versioned user data in v1. Data is USER-OWNED (data.u.<user>.*) or SHARED (data.shared.*), keyed by user, never by branch. There is no branch versioning of data at all – fork/merge/promote are code-only operations over b.<id> lenses and structurally cannot touch a datum path. Per-branch data VERSIONING (placement B) is explicitly deferred – and would now require a wholly different path scheme. - NOT a type system for Nopales. Typing lives at the tree/storage boundary; the language stays dynamic (roerick: product surface tolerates jank; the OCaml shell is where proofs live). - NOT re-opening inheritance. No INHERITS, no subtyping (storage.no-inheritance, object-model .type-system stand). - NOT a REST/GraphQL surface. The image remains the API via prims + eval. - NOT raw SQL in product code. Projections serve the image and admin tooling only.

6 borge/tree-time.borg

pricklypear-tree-time

Pricklypear book chapter: tree-time – the generation axis on the one tree. Versioned leaves keyed (branch, path, gen); history, undo, and as-of reads become storage semantics instead of per-purpose scaffolding tables. Subsumes 012 code-history, gives local-first sync its merge clock, and closes the beads-audit-gap 'data state history: NO / time travel: NO' rows. Apps stay two-dimensional: every read defaults to a slice at head.

[status: planned]

> – *agent note:* 2026-09 design discussion, three sessions of prose: (1) app-level undo in notes – notes has one write funnel (notes/doc/upsert) over pure outline transforms, making it the ideal first consumer; per-note before-images. (2) history-as-tree-of-nodes under an h.* prefix – workable without kernel change but pure copying. (3) the answer that stuck: make generation a first-class storage key on the tree itself. Geometry: three overlaid trees – path-space within a branch, branch-as-parent-pointer tree across the world, gen chains within each branch. A branch is a named fork in path-space; a gen-fork (undo + write again) is an anonymous fork in time-space. The gen tree branches exactly when undo is followed by a new write – redo and lost-timeline retention fall out of keeping both children. Prior art cross-read: beads-audit-gap note (Yegge's Beads = Dolt versioning + events + interactions + prose intent). Our answer is more elegant because the habitat collapses the stack: Dolt reimplemented a storage engine and a database; we have Postgres; Beads bolted audit on a CLI; our evaluator sits inside the store. Dolt's advantages are operationalizing (shipped GC, sync wire protocol, scale-tested diff) – each already has a named home here (jobs runner + gen-range partitions, local-first.sync manifest exchange, tree-diff merge). Downstream blast radius audit: libs/* prim surface unchanged (new optional arg only); scaffolding tables stay head-shaped mirrors; 012 code_history is RETIRED (subsumed); 017 branch_generations is promoted from cache-invalidation signal to head coordinate; mirror triggers gain one head-gen filter; the real kernel work is tree_store.ml (insert-only + head bump) + crud.ml/prims_db.ml (gen filter, optional :gen arg) + one view rewrite. Named trees-hash-consing, trees-share-nodes-not-blobs as future notes on this chapter, per one-tree.bl-blast-radius precedent. 5.0 plan pass (campaign-v1): geometry + versioned-leaves + projections + reads-as-of-gen all designed above; migration-018 subsection pins the 018_tree_versions.sql schema contract (5.1 make is deterministic); chapter wired into the book root; all stanzas stay planned (implementation flips land with 5.1/5.2/5.3).

tree-time

Generation as a storage key on the one tree: (branch, path, gen) -> node

[status: planned]

geometry

Three overlaid trees; apps see a 2D slice

[status: planned]

THREE OVERLAID TREES. The habitat's storage geometry is three parent-pointer structures, and every value resolution is a walk up one of them:

1. PATH-SPACE. Within a branch the tree is rooted: b.<branch>.* for code lenses, data.u.<user>.* / data.shared.* for data (one-tree.tree-model).

2. BRANCH LINEAGE. Branches form a tree via parent pointers (system/main -> admin/personal -> admin/dev), with merges as occasional DAG stitches (branching.borg). Lookup walks up the branch chain until it finds the newest write of a path.

3. GENERATION. THIS CHAPTER ADDS THE THIRD. Within one branch, writes form a gen chain: gen 1 -> gen 2 -> gen 3 ... The chain is linear UNTIL undo-and-rewrite walks the head pointer back and writes again, at which point the gen tree grows a sibling. Redo and alternate timelines are properties of this tree, not of any undo manager.

A BRANCH IS A USER-NAMED FORK IN PATH-SPACE; A GEN-FORK IS AN ANONYMOUS FORK IN TIME-SPACE. Same mechanism at two granularities: branches are expensive, meaningful, user-named (fork for an experiment); gens are free, continuous, system-named (every write). This self- similarity is why ONE three-way tree-diff algorithm serves branch merge, gen-axis diff (undo inspection), and local-first sync (local-first.sync's manifest exchange is the same diff with a second site).

APPS SEE A 2D SLICE. Every read in the system defaults to (current branch or ancestor, path, head gen). No package code (libs/*) changes: prim signatures stay (get 'note id); the gen axis is opt-in via new optional args and new prims. "Present day" is a read policy, not a storage property.

DATA PATHS ARE BRANCH-DEGENERATE. data.u.<user>.* is branch-free per the one-tree /data DECISION, so for data the branch coordinate collapses and gen is the only real second axis. If placement-B (per-branch versioned data) ever reopens per its recorded trigger, data becomes genuinely 3D and this same storage serves it – no second versioning scheme needed.

versioned-leaves

The storage change: tree leaves keyed (branch, path, gen); writes are append

[status: implemented]

> *[verify] smoke: ksh scripts/verify_tree_version_shadow.sh (Phase 1 shadow gate: trigger present; every shadowed live tree_nodes row's newest version is CONTENT-identical to head (envelope hash subfield excluded – deferred BORGE-1786931598); no TOMBSTONE at head for a live row; head counters never behind live version rows). Canonic tooling: ksh scripts/reconcile_tree_version_head.sh repairs the one non-head-equivalent class (tombstone-head-but-live rows are re-versioned from the live authority) and the counter heads, then re-runs the gate to confirm PASS; smoke: image/test/tree_version_shadow_test: datum create shadows one row; datum update appends + as-of read returns old body; datum delete appends TOMBSTONE; fn code-path bumps branch_generations*

NEW TABLE tree_versions, keyed (branch_id, path, gen):

gen is the tree-scoped (branch-scoped for b.* paths; tree-scoped for branch-free data.* paths) monotonic counter ALREADY COUNTED by branch_generations (migration 017) and the tree_generations variant proposed with it. 017 was built as a cache-invalidation signal for remote-eval.caching; this chapter promotes the counter to the storage key – same counter, second use, exactly as local-first.sync's last-synced merge base is the same counter's third use.

WRITES ARE APPEND. update and delete never rewrite a row: - update writes (branch, path, gen+1, new body). - delete writes (branch, path, gen+1, TOMBSTONE) – a tombstone row is the marker, never a DELETE. This is what makes undo-of-delete and audit-by-state-diff free. - create is identical (the first version row). Structural sharing falls out of append-only without content addressing: a write touches exactly the changed paths; every other path's newest row is untouched. The tree's nodes are our chunk granularity –

habitat data is grain-sized (notes outlines, todos, defs are KB-scale), so per-node sharing is near-optimal where Dolt needs chunk-level sharing inside large tables. (Hedge recorded: a 50MB table-shaped datum updated one field at a time pays O(node) per write; the culture says data is grain- sized, and content addressing – one-tree.tree-model "content-addressing later" – is the physical dedup answer if that changes. Hash-chained gens (tamper evidence) are NOT required: the image writer is trusted; this chapter does not build a Merkle-DAG, it uses hash comparison for diff, not integrity.)

READ PATHS. Leaves may carry precomputed subtree hashes (one-tree.tree-model: hash over canonical body, root hashes compose) so tree-diff across gens is hash-first: equal hash = prune, differ = walk. This is the existing subtree-hash plan with a second consumer (the first was branching merge; the third is local-first sync).

MIRROR PRESERVATION – the bl-blast-radius contract applies in full: a scaffolding-table writer and a tree writer see IDENTICAL history, INCLUDING writes made through the other path and from AFTER v1 shipped, or the swap corrupts merge bases. The triggers must keep the tables and the versioned tree in lockstep both ways, as migration 009 established and this chapter extends into the time dimension: table UPDATE/DELETE both write a new version row AND keep the head-shaped mirror current.

migration-018

The 018_tree_versions.sql schema contract (design, plan pass)

[status: planned]

THIS IS THE PLAN-PASS SCHEMA CONTRACT for migrations/018_tree_versions.sql – the file does not exist yet; 5.0 designs it here so 5.1 (make versioned-leaves) is deterministic, mirroring how 4.0 pinned 015_jobs.sql in borge/jobs.borg.

TABLE tree_versions – append-only history, one row per (branch_id, path, gen) write:

branch_id uuid NULL for branch-free data.* paths (otherwise the owning branch); path ltree NOT NULL (same encoding as tree_nodes: b.<hex(branch_id)>.fn.<label> / data.<type_name>.<id>); gen bigint NOT NULL (the gen counter – see below for the per-path-class source); kind text NOT NULL (fn | type | route | datum); type_name text (datum only); body jsonb NOT NULL (the node envelope {v,kind,path, type,body,author,doc,hash}; TOMBSTONE is a reserved body marker for delete – see below); hash text NOT NULL (sha256 over canonical body; precomputed subtree-hash consumer); author text NOT NULL; created_at timestamptz NOT NULL DEFAULT now() (write time; immutable per version row). PK (branch_id, path, gen) – unique per write. branch_id NULL allowed only on data.* paths; enforce with a CHECK that branch_id IS NOT NULL when path <@ 'b.*'.

COVERING INDEX for head/projection reads: (branch_id, path, gen DESC) A b-tree range scan returns the newest gen per path in one pass (projections subsection). No join needed at habitat scale.

GEN COUNTER SOURCE, per path class (reads-as-of-gen): - code paths (b.<branch>.*): branch_generations (migration 017) with its per-branch bump discipline IS the head counter; each new version row takes branch_generations.generation+1 and the counter bumps. The 017 triggers already fire on the scaffolding writes bound to these paths. - data.* paths: branch-free, so a TREE-WIDE tree_generations (bigint) row is the head; every data write takes gen+1 (the 017 root-row bump discipline generalized to one row). Deliberately NOT per-path – under (branch_id, path, gen) the per-path order is implicit; the global counter keeps undo / diff ordering tree-wide and matches the local-first.sync merge clock.

TOMBSTONE: delete writes (branch_id, path, gen+1, body = {v:1,kind,path,type,body:null,author,doc:null,hash:<hash of tombstone marker>}) – a row, never a DELETE. A path is ALIVE at gen when its newest row at or below head is NOT a tombstone. A tombstone row

IS the head-shaped mirror's delete signal (mirror rows DROP; the history row remains).

SUBTREE HASH: hash is over the canonical body (as today); the chapter's content-addressing note stays deferred – this column is the diff-first-prune comparison key, not a Merkle chain.

PARTITIONING for gc (gc subsection): tree_versions is declared RANGE PARTITIONED BY list(gen/1000) with lazy partition creation; DROP PARTITION is the retention path. The 018 migration creates the table + base partition only; gen-window partitions are created by the retention worker.

ALL ADDITIVE per migrations.borg additive-only + image- applied-by-image discipline; 018 applies idempotently and registers in schema_migrations. Nothing reads this table until Phase 2 of coexistence-plan flips the PP_* flag; the scaffolding mirrors + tree_nodes remain the source of truth through Phase 1 dual-write shadow.

projections

Head-shaped scaffolding stays bit-identical: views gain one predicate; mirrors gain one filter

[status: planned]

> *[verify] smoke: image/test/code_history_tree_test: code-history/code-diff read from tree_versions (below-head before-images, newest-first; rel function_defs / op UPDATE / author; code-diff vs nth-newest; in-range/out-of-range); smoke: external history_test (012 regression): redefine records old body, merge-clobber records history, additive insert has NO history, rollback leaves none, code-diff smoke – all green under the tree-backed source*

THE VIEWS ARE THE API. Reader concentration from the projection era is what this change rides down:

- tree_data_rows and friends gain one predicate: greatest (branch, path) row with gen <= head, and no tombstone as newest. A b-tree range scan ((branch_id, path, gen DESC) covering index) – one index range scan per read, no join, well inside the image.borg per-page DB-cost ceilings at habitat scale.

- The scaffolding tables (function_defs, type_defs, view_bindings, data_rows) STAY HEAD-SHAPED. Gen history lives inside the versioned tree only; the mirrors reflect head, as they do today. Every residual reader, fork-copy path, admin page, and /data browser sees a bit-identical HEAD. Zero package code changes.

- WRITE-then-READ within one request must read its own write – crud.ml's in-transaction reads already run on the bound connection (Io_lwt.Db.current_conn); the head pointer for any in-flight read is the transaction's gen, so this property is inherited from the existing transaction discipline, not re-derived.

- The mirror triggers (009 both directions, 020 AST projection) gain ONE further condition: head-shaped targets refresh only when the versioned write is the new head. Append-side, each write is by construction the new head of its (branch, path), so the filter is trivial; the condition matters for future restore/head-move operations.

WHAT LEAVES: the 012 code_history triggers and table. Their job (before-images of code rows at writer-txn fidelity) is subsumed: a history read = read the version row at gen-1. code-history and code-diff prims KEEP THEIR SIGNATURES and re-implement over tree_versions (see reads-as-of-gen). The 012 table itself: read-only archival during phase 2; dropped in a later migration once equivalence is verified (one verifier script: sample N names, compare 012 rows' bodies to tree_versions bodies at matching changed_at).

PHASE-3 MAKE (landed, 5.2): the code-history / code-diff reimplementation over tree_versions is DONE – Store.list_code_history routes to tree_versions

via the versioned read surface (versioned_history below-head), with the 012 table as the fallback for pre-shadow (pre-019) names so no historical depth is lost during the coexistence window. The below-head filter preserves the 012 before-image semantic exactly: an insert-only fn has no history until it is rewritten or deleted, and the newest entry is the state just before the latest change ("read the version row at gen-1"). re-implements the two prims with signatures unchanged; rel is derived from the code-path kind (fn?function_defs / type?type_defs / route?view_bindings), op=DELETE on below-head TOMBSTONE rows else UPDATE. Verified by image/test/code_history_tree_test + the existing history_test stays green (additive-insert-no-history included). STILL PLANNED (Phase 2): the tree_data_rows head-predicate view rewrite behind the PP_ flag + the equivalence verifier + 012 archival/drop.

reads-as-of-gen

The new prim surface: optional gen coordinate + four new prims
[status: implemented]

> *[verify] smoke: gen-now returns the current branch generation (migration 017 ancestry-walked counter); smoke: (gen-read path gen) returns the node body at gen as version JSON – absolute data./b. paths AND relative logical suffixes crossed through the branch lens chain (closest-wins); nil when unversioned; smoke: (gen-diff path ga gb) returns 'same' when both leaves hash-identical, else a {path,a,b,same,delta} node-granular diff (shallow body key walk on mismatch); smoke: (undo path [n]) restores the value at head-n as a NEW write at head+1 (restore-by-write: the restore itself is versioned + redoable) for the datum path class; smoke: (tree/get path :gen N) resolves the node at that gen (versioned read); omitted = live head; smoke: image/test/reads_as_of_gen_test: tree/get :gen reads-as-of; gen-read absolute path at head + as-of; gen-diff node-granular + self-diff 'same'; undo restore-by-write + redo + n-step deep*

EXISTING PRIMS GAIN A FALLBACK COORDINATE, NOT A REQUIRED ONE. get / rows / tree_get take an optional trailing :gen N argument; omitted means head. No existing call site in libs/* or the kernel changes meaning.

NEW PRIMS (small surface, all ordinary prim_fns):

(gen-now) -> current tree gen (gen-read path gen) -> node body at gen, crossing the same branch lens rules as head reads (gen-diff path gen-a gen-b) -> node-granular diff: hashes first, walk on mismatch (same algorithm branching merge + local-first sync use) (undo path) / (undo path n) -> restore the value at head-n as a NEW write at head+1. Restore-by-write, not head-pointer manipulation: the restore itself is versioned, so undo is lossless by the same argument as restore-by-redefine in code-history (branching.borg). Redo = (undo path) again on the restored state via the gen chain; no separate redo stack.

WHERE THE HEAD POINTER IS, per path class: - b.<branch>.* code paths: per-branch – the branch_generations counter IS the head. Undo on code paths is branch-local: read (branch, path, gen-1), write to (branch, path, gen+1) on that branch. - data.* paths: branch-free, so the head pointer is a tree-wide data generation (the 017 migration's root-row bump discipline generalizes to one tree_generations row). Undo on data paths is per-path: it moves no global pointer, only appends a restored value for that one path. NOTHING about multi-user safety changes: Andrea's undo of her note is an append to (data.u.andrea.note.<id>, gen+1); Beth's head is untouched because the head is a counter, not per-path state.

EVAL-SCOPE UNDO IS NOT A PRIM. "Undo my session's last N writes" is the habitat-events stream (event journal of eval forms) correlated with paths, then a sequence of per-path undos – rerun bookkeeping, not storage. This chapter deliberately does NOT build cross-path transaction-undo; habitat-events + per-path (undo path) compose it when both exist.

COST ACCOUNTING (agent guidance): the first gen-as-of read pays one index range scan; the authoritative cost playbook applies – gen-diff of large subtrees belongs in the read tool you call, not pasted wholesale into eval context.

consumers

What this subsumes or feeds, in dependency order
[status: planned]

> *[verify] smoke: (code-restore name [n] [owner/branch]) re-writes a code node (fn/type/route) at head-n as a NEW write at head+1 through the code write surface (upsert_fn / upsert_type / upsert_route): reverse mirror re-populates function_defs / type_defs / view_bindings, the restore is itself versioned + redoable (restores the value BEFORE the latest change; n is row-count steps back, not gen arithmetic); smoke: (code-restore name [n] [owner/branch]) errors cleanly – no such code path / no version history / tombstone at n steps back (use tree/delete) / no body / unsupported rel / out-of-range n – never a crash; n<1 and n>=history-length rejected; smoke: image/test/code_restore_test: fn n=1 rewinds body to body-2, n=2 to body-1; type n=1 rewinds fields; route n=1 rewinds handler + visibility; insert-only has no state; unknown name errors cleanly; smoke: NOTES UNDO – the FIRST APP CONSUMER is real (tree-time.consumers details): notes has ONE write funnel (notes/doc/upsert), so undo needs NO per-app journal – the substrate keeps the before-image. The note page toolbar gains an Undo button (action=undo in libs/notes/lib.pp) that does ONE per-path (undo path) call and redirects back; an error-string return (no history / no value) leaves the note unchanged. Undo is KIND-AWARE: a note is a hierarchical node (kind=note via upsert_hier), and restore-by-write routes back through upsert_hier preserving the original kind + payload envelope – a naive upsert_datum restore would silently rewrite the payload marker to datum (the kind-column/payload mismatch this consumer exposed). image/test/reads_as_of_gen_test: 'undo kind-aware (note payload not datumed)' writes two note versions through upsert_hier, (tree/undo path) restores title v1, and asserts node kind stays note AND payload-»'kind' stays note (not datum).; smoke: image/test/reads_as_of_gen_test: 'undo kind-aware' – after (tree/undo path) on a two-version note, live tree_get returns title v1, the JSON node kind is still note, and the live tree_nodes payload marker kind is still note (not datum).*

SUBSUMES: branching.code-history (012). The separate before-image trigger table exists because the tree did not keep history. Now it does. code-history / code-diff / code-restore become reads of the tree; restore gains a real prim (code-restore = gen-read + define, exactly the lossless-redefine pattern the 012 design documented by hand).

FIRST APP CONSUMER: NOTES UNDO. The motivating case (design discussion 2026-09). Notes has ONE write funnel – every mutation ends at notes/doc/upsert over pure outline transforms – so app-level undo needs NO per-app storage: - notes/doc/upsert-in records nothing; the substrate keeps the before-image. - (undo (node-path 'note id)) in place of any history journal; the notes package keeps at most a UI-facing "undo the last change to THIS note" button wired to one per-path call. - Leaf-vs-whole is free: undo of one outline NODE and undo of the note SUBTREE are the same prim at two path granularities, because the outline is a subtree of tree leaves. The earlier candidate designs (JSON blob notes_history table; h.* prefix spine of copied subtrees) are SUPERSEDED and recorded here only so a future reader does not re- derive them – both were copy-based schemes working around a substrate that discarded before-images.

FEEDS: branching.branch-status (IMPLEMENTED 2026-08-28). Branch status status (clean/ahead/behind/diverged/synced) is a hash-first read over tree_versions keyed on a base_gen merge-base coordinate – the first branch-

axis (not gen-axis) consumer of the versioned leaves, and the retirement of list_overrides' name-presence classification.

FEEDS: local-first.sync (planned). Sync's merge base was already defined as (branch, generation) snapshot pins; with gen as a storage key, "common ancestor at pin" is a READ, not a snapshot artifact. The 017 counter's three uses – cache invalidation, merge base, and now storage key – are one counter. local-first's data-sync section gains one companion line: sync reconcile reads the data gen chain; it does not version data per-branch (that non-goal stands).

FEEDS: habitat-events (planned note garden/design?slug=habitat-events-borg). Orthogonal by design: events answer OPERATIONS questions (who evaluated what form, when); tree-time answers STATE questions (what did the world look like). The two join on path+gen: an event row may reference the gen it wrote, making the audit trail (scoreboard: agent audit PARTIAL -> agent- readable by construction) navigable from event to state. "Stream not tree" stays right for events; this chapter is the tree half of the full Beads-equivalent picture: events for op-log, tree-time for versioned state, forge for intent – one merge algorithm across all three.

SCOREBOARD EFFECT (beads-audit-gap): data state history moves NO -> YES-STRUCTURAL; time travel moves NO -> YES (the degenerate gen read).

gc

Retention: gen-range partitions, jobs-runner rollup, policy as habitat data
[status: implemented]

> *[verify] smoke: migration 022_tree_retention.sql applies clean + idempotent on a dev PG with 018-021 already applied (image-applied, version 22 in schema_migrations): creates tree_retention_policy (path_class CHECK code|data, type_name NULL= whole class, keep_windows >= 1, UNIQUE(path_class,type_name)) and tree_versions_retain(path_class, keep_windows) – an idempotent, conservative rollup+drop worker that computes a whole-class floor = GREATEST(head_gen - keep_windows*1000, 1000), CHECKPOINTs the newest in-retained-past state of every fully-retired path (whole history < floor) to a row at gen=floor, then DROP PARTITIONs every lazy gen-window entirely below the floor (never the base gen_0 window).; smoke: (retention-policies) -> VList of policy JSON – empty on a policy-free habitat (keep-everything default). (retention-policy-set path_class keep_windows) / (retention-policy-set path_class type_name keep_windows) upsert a whole-class (type_name NULL) or per-type row; (retention-delete-policy path_class [type_name]) removes it. Admin-only (require_admin); anonymous raises.; smoke: (retention-run [path_class]) drives the worker per path class that has an explicit whole-class policy (type_name IS NULL): runs tree_versions_retain, returns VList of (path_class, dropped_windows, checkpointed_paths). Path class with NO whole-class policy is a keep-everything no-op (never ad-hoc deletion). Verified live on the dev habitat: (retention-policy-set "code" 3) then (retention-run "code") dropped 16 gen-windows and checkpointed 4473 code paths; policies deleted after to restore keep-everything.; smoke: The retention worker runs ON THE JOBS RUNNER (migration 015) – boot.ml jobs_runner_loop gates a periodic retention_sweep by wall-clock (default 3600s, PP_RETENTION_SECS override) which calls Store.retention_run for every path class and logs per-class dropped/checkpointed counts. On a policy-free habitat the sweep is a cheap no-op SELECT. This is the coexistence-plan PHASE 4 gate that flipped the gc subsection to implemented (the chapter itself stays planned until the Phase-2 scaffolding read-switch + equivalence verifier tail in the projections subsection lands - see coexistence-plan STATUS 5.4 reconcile).*

NO NEW SUBSYSTEM. Dolt ships dolt_gc because it owns its chunk store; here Postgres owns vacuum. GC is three existing pieces composed:

- PARTITIONING: tree_versions is partitioned by gen range windows (e.g. 1000-gen ranges, created lazily). Physical removal is DROP PARTITION – instant, no vacuum scan. PG-native; the chunk-GC problem Dolt engineered against does not exist for a partitioned table.

- RETENTION POLICY IS HABITAT DATA. Policy rows declare per-path-class retention (code paths: keep all history, it's small and it IS the audit trail; data paths: per-type policy, default keep-everything-until- a-policy-exists). habitat-events' "retention is habitat data (policy rows + rollup job on the existing jobs runner), never ad-hoc deletion under disk pressure" applies verbatim; the jobs runner (migration 015) executes.

- ROLLUP, NOT SILENT LOSS. Before a window is dropped, surviving state collapses to a CHECKPOINT row at the window's boundary gen: the newest version of each path in the window is rewritten at the boundary, so reads as of ancient gens still resolve (to the checkpointed state) and head reads never notice. "Nobody gets everything forever – the audit claim survives at coarser grain."

ORDERING: GC lands AFTER reads-as-of-gen and the consumers bed in. The first long pole is growth FROM code paths, which are tiny; habitat scale makes early compaction premature. The retention job is a TODO until a path class outgrows its welcome – measured via /timing-style storage accounting, not vibes.

SHIPPED 2026-12 (campaign 5.3): the retention worker is REAL and runs on the jobs runner – migration 022 (tree_retention_policy + tree_versions_retain), the four admin-gated retention prims (retention-policy-set / retention-delete-policy / retention-policies / retention-run), and the boot.ml jobs-runner sweep gated by wall-clock + the keep-everything default. Whole-class policies are the v1 gate; per-type rows are recorded for future finer-grained work but the shared gen-window floor stays whole-class (tree_versions is a global table). The coexistence-plan PHASE 4 condition – "the retention worker runs on the jobs runner" – is met, flipping the gc subsection to implemented. (The chapter as a whole stays planned: the Phase-2 flag-guarded scaffolding read-switch + equivalence verifier + 012 archival/drop tail, owned by the projections subsection, remains open – see the coexistence-plan STATUS 5.4 reconcile.)

coexistence-plan

Phased, additive-only, flag-guarded; nothing existing is rewritten in place

[status: planned]

PHASE 0 (this chapter): spec. No code.

PHASE 1 – DUAL-WRITE SHADOW. DONE (campaign 5.1, loops 27/28): the migration-018 schema + the 019 additive dual-write shadow trigger landed. Every tree_nodes write (insert/update/delete->TOMBSTONE) appends a version row in ADDITION to today's writes, allocating its head gen atomically per path class (branch_generations for code b.* paths, the tree_generations singleton for data.* paths); 020 refines the append so a no-op mirror echo (unchanged content) returns BEFORE allocating a gen – one logical write is never double-counted. Nothing reads the new table for a live read yet. Verify: scripts/verify_tree_version_shadow.sh (Phase 1 gate: every shadowed live row's newest version matches head) upgraded in 5.2 to the Phase-2 equivalence gate.

PHASE 2 – READ SWITCH, FLAG-GUARDED. MOSTLY DONE. The gen coordinate landed as an UNGUARDED additive surface, not a flag-guarded mirror re-route: store versioned_head / versioned_history + (gen-now), then (tree/get path :gen N) / (gen-read path gen) / (gen-diff path ga gb) / (undo path [n]) (5.2, c9c49dc). The PP_* flag-guarded SCAFFOLDING read switch is the tail that remains STILL PLANNED, owned by the projections subsection: the tree_data_rows / scaffolding-mirror head-predicate view rewrite behind the PP_ flag + the 012 equivalence verifier (sample N names, bodies equal)

+ 012 archival/ drop. code_history triggers keep firing until equivalence holds continuously for a soak window.

PHASE 3 – CONSUMERS LIGHT UP. DONE except the 012 archival/drop (see PHASE 2 tail). code-history / code-diff re-implemented over tree_versions (signatures unchanged; 012 before-image table retained as pre-shadow fallback, 5.2, 72d5380); (gen-read)/(gen-diff)/(undo) land; the code-restore prim (code-path analogue of undo, 5.3 loop 36); notes undo is a real app consumer (toolbar Undo button, one per-path (undo path) call + kind-aware upsert_hier restore – 5.3 loop 37, 89b0555). The 012 table stays read-only archival until the equivalence verifier in PHASE 2 clears.

PHASE 4 – GC + CHAPTER COMPLETE. DONE (5.3 loop 37, 89b0555): partitioning + retention worker per the gc subsection – migration 022 (tree_retention_policy + tree_versions_retain), the four admin-gated retention prims, and the boot.ml jobs-runner retention_sweep gated by wall-clock. The PHASE 4 GATE – "the retention worker runs on the jobs runner" – is met and flipped the gc subsection to implemented.

STATUS (5.4 reconcile): Phases 1, 4 fully done; Phase 3 done except the 012 archival/drop; Phase 2 done except the flag-guarded scaffolding read-switch + equivalence verifier. The remaining open work is the Phase-2 tail, which is owned by the projections subsection (still planned) – this subsection stays planned until that tail lands, mirroring how projections/consumers stayed planned with their open items recorded.

ALL MIGRATIONS ADDITIVE per conventions (new table, new views, new columns – never rewrite payloads; 017's WHERE NOT EXISTS idempotence style). Downstream blast radius, audited in design: libs/* zero changes; scaffolding readers zero changes; habitat-events unaffected (append- only stream either way); local-first gains a read enhancement (merge base as read), no redesign.

non-goals

What tree-time is NOT

[status: planned]

- NOT branching data. The one-tree /data DECISION (single-head, user-owned, SPATIAL not TEMPORAL) stands at the CONCEPT level; this chapter adds TEMPORAL STORAGE-KEYS invisible to users – one head per path, many retained gens below it. The DECISION's reopen trigger (a user forking their own data to experiment and merge back) is a distinct feature; this chapter is compatible with it but does NOT build or reopen it.

- NOT a Merkle-DAG / tamper-evident ledger. Hash-chained gens exist only if a future untrusted-writer scenario demands them (local-first's untrusted-client punt). Hashes here serve diff, not integrity.

- NOT the habitat-events stream, and NOT replaced by it. Operations-audit and state-history answer different questions; one emissions table and one versioned tree.

- NOT eval-scope or cross-path transaction undo as a storage primitive. (undo path) is per-path; session scope composes from habitat-events correlation later.

- NOT a rewrite of libs/*, scaffolding tables, or the prim ABI. Optional args only; head-shape preserved; existing call sites mean exactly what they meant.

- NOT content addressing. Physical dedup of identical bodies is deferred to one-tree.tree-model's existing "content-addressing later" note; append-only gives the structural sharing this design needs without it.

- NOT rename-tracking. Path is part of the key; a rename is delete+create in history space. Same posture as git (detection over tracking); the blast-radius walking problem for historical names is accepted.

7 borge/branching.borg

pricklypear-branching

Pricklypear book chapter: branching
[status: partial]

> – *agent note:* 2026-08-02 status reconcile: agent-promote, package-updates, branch-browser-ui ? implemented. Still open: schema-authority (type_defs merge), ast-nodes (design).

branching

Branches as the fundamental organizational primitive: code branches, shared data, fork/merge
[status: partial]

Branches are to Pricklypear what files are to Unix: the fundamental organizational primitive. Everything is a branch; everything else is built on top of that.

STORAGE (one Postgres, not one DB per branch): - branches(id, parent_id, owner, name, ...) - function_defs / type_defs / view_bindings each keyed by (branch_id, name|route) - data_rows has NO branch_id – shared data No separate schemas/tables per branch. No Postgres INHERITS (see storage.no-inheritance).

KEY DISTINCTION: branches are for CODE, not data. - BRANCHED: function definitions, type schemas, view/route bindings. - SHARED: data_rows (todos, notes, bible, ?). Alice's experimental branch renders against REAL shared data. She forks code, not data.

TWO FORK SHAPES: - EMPTY child (personal garden): parent pointer only; inheritance via recursive CTE. Main package updates stay visible unless overridden. - FULL fork (experiment): copy code-rows from parent (cheap snapshot). Parent updates do not appear until merge.

ROLES: system/main package defaults (inheritance root) <user>/personal garden (boot default; long-lived pins) <user>/dev optional workshop (empty child of main; active product work intended to promote) <user>/<name> experiments (full fork when isolation from evolving main is required)

AUTHORITY (Nopales vs kernel) – see package-updates: Kernel (OCaml/migrations) ? git is source of truth Package Nopales ? Postgres branches are live source; git holds snapshots Boot seed ? additive into system/main only (never clobber existing) Explicit reseed ? git libs may overwrite main when an admin asks

Effective definition lookup (CLOS override): walk parent chain, closest definition wins. Writes (define/route) always hit the ACTIVE branch only.

fork

Forking a branch
[status: implemented]
(fork 'main 'alice/experiment)

Implementation: 1. INSERT INTO branches (id, parent_id, owner, name, ...) VALUES (new_uuid, main_id, 'alice', 'experiment', ...) 2. INSERT INTO function_defs (branch_id, name, body, author, updated_at) SELECT new_uuid, name, body, author, updated_at FROM function_defs WHERE branch_id = parent_id 3. Similarly for type_defs, view_bindings

Cost: O(num code rows in parent). For ~100 fns and ~20 types, a few hundred row inserts. Lands in well under a second.

Forking does NOT copy data table rows. The forked branch's functions operate on the same shared event rows as the parent.

[verify] test: image/test/primitives_test.ml – 48 alcotest cases; build: dune build @all; smoke: fork creates a branch and copies function_defs; smoke: override-walk resolves child overrides before parent; branches isolate writes

merge

Merging a branch into its parent

[status: implemented]

(merge 'alice/experiment 'alice/main)

Policy: - Default: admin-only merges to main, per-user can merge into their own branches freely. - Expandable later (PR/review flow).

Implementation (Store.merge_branch, image/lib/store.ml): upserts all function_defs rows from source into target via INSERT ... ON CONFLICT (branch_id, name) DO UPDATE, wrapped in a SERIALIZABLE transaction. Initial cut copies the full set; diff-based merge (only changed rows, per-function conflict resolution) is not yet implemented.

CONFLICT REPORT (v1: report-only, never blocks): before the upsert, merge computes names where BOTH source owns a row AND target owns a row whose updated_at is newer than source's (target moved independently since the lens diverged). Result string carries them: "merged N rows (M conflicts: a, b, c)" Resolution stays last-write-wins (source body lands); the report tells the human what was clobbered, and code-history makes the clobbered target body recoverable. Blocking/require-resolution merge is a later PR/review-flow concern, not v1.

SCOPE: merge copies function_defs only. It MUST NOT copy type_defs (schema authority is main; see schema-authority) and MUST NOT copy view_bindings blindly (route hijack risk). Routes travel with named functions through promote instead (see promote).

type_defs merge: not implemented by design in v1. A branch cannot propose a schema change through merge; schema changes land via migrations applied on boot (see migrations.additive-only) and are visible to all branches on next lookup.

[verify] test: image/test/primitives_test.ml – fork/merge/promote alcotest cases; build: dune build @all; smoke: merge upserts changed rows; merges into system/ require admin; smoke: merge result string lists conflict names when target moved newer; smoke: merge copies no type_defs and no view_bindings rows*

diff

Structural divergence between two branches (AST-aware, not textual)

[status: implemented]

– *agent note:* 2026-08-16 ralph loop 19: implemented + verified. Store.diff_branches (store.ml), (diff from to) prim (prims_db.ml), GET /diff?from=&to= private page (http_branches.ml, http.ml route) wired; ast_diff 27/27 green, full dune build @all + runtest exit 0. 2026-08-14: gap surfaced testing personal-vs-main divergence. merge_branch is naive full-copy with explicit TODOs (diff-based merge, conflict detection); diff is the primitive those TODOs consume. AST-awareness chosen because function_defs.body is ONE expr node (not a statement list), JSONB-tagged structurally - see lisp-interpreter.ast-diff.

[verify] build: dune build @all; test: lisp/test/ast_diff_test.ml – same/modified over all 11 real expr constructors (Var Lit App Let Letrec If Lambda Prim Seq Quote Define); test: App.args and Letrec.bindings use list-LCS

keyed on analyze.ast_hash so insertion mid-sequence does not mark every following element changed; test: top-level ast_hash equality short-circuits the walk for unchanged rows; smoke: (diff 'system/main 'admin/personal) lists added/removed/modified names without scraping /bindings HTML; smoke: /diff?from=system/main&to=admin/personal renders Modified rows with per-ctor AST deltas; Added/Removed show pp_expr of the lone body

PROBLEM: testing divergence between a personal branch and main is currently manual – (list-bindings) under each (checkout ...) and eyeballing. merge_branch (see merge) copies ALL function_defs source->target with three open TODOs: diff-based merge (only changed rows), conflict detection (parent moved same name since fork), and per-function resolution. diff is the primitive those TODOs consume, and the thing a human/agent reads before promoting.

(diff 'system/main 'admin/personal) -> VList of change-dicts, one per divergent name (no row for unchanged – the common case): {name kind status from-updated to-updated} kind :: fn | type | route status :: added | removed | modified

LAYERING (two stages, at the seam the codebase already has): 1. ROW CLASSIFICATION (SQL, one round trip): both effective views via the SAME recursive CTE that list_function_names_meta / list_packages / search_function_bodies use (closest-ancestor-wins). FULL OUTER JOIN on name, classify each as added = in to, not in from removed = in from, not in to modified = both, AND from.body IS DISTINCT FROM to.body Scope mirrors merge_branch: function_defs + type_defs + view_bindings (NOT data_rows – shared, branch-free per branching.data). Conflicts fall out for free: this is the inverted conflict_sql already in merge_branch. 2. AST DELTA (OCaml, Modified rows ONLY): parse both bodies via expr_of_json, walk with lisp/lib/ast_diff.ml (see lisp-interpreter. ast-diff). Never runs on Added/Removed (nothing to compare – show pp_expr of the lone body) or on Same (short-circuited).

AST-AWARENESS IS A PROPERTY, NOT A NICETY. function_defs.body is ONE expr node (Lambda body, not a statement list), JSONB-tagged structurally ({"if":...}, {"lambda":...}, {"app":...}). A textual diff over the JSONB ::text would be unreadable; a line diff over pp_expr output would jitter on whitespace and miss structural moves. The diff is structural over the expr type:

ctor differs (Var -> Lambda) = Replaced same ctor, fixed-arity children = Node, recurse positionally (If test/then/else; each Seq a/b; Lambda params/body; Let name/ child val/body; Define name/val; Quote body; its Var s; Lit v) own delta same ctor, list children = Node with a list-LCS step over the children plus a before recursing into matched pairs: moved/ - App.args (head + args list) added - Letrec.bindings (keyed on binding name) list handled leaf value differs (Var s, Lit v) = Replaced

The 11 real expr constructors (ast.ml): Var, Lit, App, Let, Letrec, If, Lambda, Prim, Seq, Quote, Define. The Quasiquote / Unquote / Unquote-Splicing mentioned in lisp-interpreter. ast are reader-level sugar that desugars before persistence (see macros) – they do not appear in function_defs.body and need no diff case.

FAST PATH: analyze.ast_hash (sha1_hex of Reader.pp_expr) is already the content identity. Compare from/to hashes first; if equal, skip the walk entirely (returns Same). The 90% case (unchanged defs between branches) costs one hash compare per row, not a tree walk.

SCOPE & TYPE/ROUTE HANDLING: - function_defs: full AST diff as above. - type_defs: diff the 'fields' jsonb array with the same list-LCS (field declarations are positional lists, not expr trees; no ast_diff involvement). - view_bindings: tabular (route, handler) pair sets – divergent pairs are added/removed rows, no body to diff. Stays in SQL. Schema changes land via migrations (see schema-authority), never via diff/merge.

NON-GOALS (v1, honest): - No rename detection. A bound-var rename

x->y surfaces as a Replaced at the binding site (Lambda.params / Let name / Letrec binding name) AND a Replaced at every reference site (Var x -> Var y). git doesn't do this for free either; real rename detection needs the 3-way base (fork point), which is the natural v2 once code_history before-images + branches.last_synced are wired as the base. - No alpha-equivalence. Bound names are NOT normalized before comparing – a genuine rename is meant to be visible, not hidden. - Param order matters. (lambda (a b) ...) vs (lambda (b a) ...) is a positional child delta, NOT "renamed params".

DEGRADED RENDER PATH: if the /diff page does not want to render the structured delta tree, fall back to a unified line diff over Reader.pp_expr from / Reader.pp_expr to. This is the existing simple_text_diff shape (see code-diff) applied to two live bodies instead of a history entry. Always available; never the primary surface.

WIRE-IN: - Store.diff_branches ~from_id ~to_id (image/lib/store.ml, beside merge_branch): the SQL stage + Modified-row (from_expr, to_expr) pairs ready for the image layer. - (diff source target) prim (image/lib/ prims_db.ml, beside code-diff): returns the VList of change-dicts (summary level). The structured AST delta is consumed in-process by the /diff page renderer (Ast_html + Ast_diff), NOT exposed as a separate prim in v1. A programmatic (diff-ast name from to) prim is a v2 addition if agents need the delta tree as Nopales values. - /diff?from=&to= private page (image/lib/ http_branches.ml, sibling to /bindings): three-column row table; Modified rows expand to the AST delta overlaying Ast_html.pp_expr_html. Future "promote selected" off diff rows IS the merge TODO (diff-based merge) in disguise.

DOWNSTREAM CONSUMERS (the point of building it): - merge TODO "diff-based merge (only changed rows)": merge calls diff, upserts only rows whose status != same. - merge TODO "conflict detection": the 3-way base is the base_gen coordinate of branch-status (tree-time made it a READ, superseding the code_history / timestamp plan recorded here).

branch-status

Git-style clean/ahead/behind/diverged status as ONE derived read of the tree-time substrate

[status: implemented]

PROBLEM: branch status is computed AD HOC, per surface, as name-presence joins on the scaffolding tables. Store.list_overrides classifies every own function_defs row as new | override | main newer by NAME EXISTENCE + updated_at heuristics – never by content. Consequences, all observed: - a full fork marks every function "override" though every body is identical - after promote, the source pin stays IDENTICAL to main but reads "override" (or "main newer", the timestamp flip) forever - nothing can answer "does this branch actually diverge?" without scraping /diff - merge's conflict heuristic is updated_at string comparison; there is no fork point anywhere in storage (branches.last_synced is an unused timestamp) No incremental fix works: each surface re- derives branch semantics itself. The fix is to stop deriving branch semantics from row geography and start deriving it from CONTENT at GENERATIONS – the tree-time substrate that already exists.

MODEL (two coordinates, additive): - base_gen: NEW COLUMN on branches (bigint). At fork, base_gen = parent head gen (branch_generations.generation of the parent at fork time, parent chain walked; 0 for branches forked before the column exists whose parent has no own writes). After a merge or promote lands on the parent, base_gen ADVANCES to the merged head – this is git's moving merge-base, and it RETIRES branches.last_synced (timestamp), which was designed for this job in the code_history era and never wired. - head gens: already counted per branch by branch_generations (migration 017), the same counter tree-time promoted to a storage key.

Because tree_versions (018-021 shadow) is append-only with a content hash per version row, "value of path P on branch B at gen G" is a READ, not a

snapshot: newest version row for (resolved-owner-of-P, P) with gen <= G, non-tombstone. Resolution for uncopied gens uses the same closest-wins branch-lens rule as head reads.

THE STATUSES (per name, fn | type | route): b = branch value at own head, p = parent-chain value at parent head, a = value at base_gen (absence = tombstone/never-existed; comparisons are HASH comparisons, ast_hash for fn bodies per diff's fast path): clean no own write since base, b == p (inherited; may differ from a – that is normal upstream movement, not dirt) ahead-new own write; parent has never had the name (a absent) ahead own write; b != a, p == a behind no own write since base; p != a (upstream moved) diverged own write; b != a AND p != a AND b != p (the genuine conflict set merge reports) synced own write; b == p (identical pin – post-promote or package-pin noise; the unbind candidate class, replaces "override") Git mapping: clean = up to date, ahead* = committed-locally, behind = remote moved, diverged = conflict, synced = cherry-picked downstream already. "dirty" = anything but clean|behind (own writes exist).

ONE COMPUTATION: Store.branch_status ~branch_id -> rows {name kind status branch_hash parent_hash base_gen head_gen} Hash-first per tree-time: compare hashes, prune on equality; bodies are fetched ONLY for rendering (Modified rows go through lisp/lib/ast_diff.ml exactly as /diff does today). One round trip per path class, same recursive-CTE chain walk style as diff_branches – but against tree_versions, not function_defs.

CONSUMERS (every current status surface becomes a rendering of branch_status, none keeps its own classifier): - /branches list: "overrides" count becomes dirty count (ahead-new + ahead + diverged); synced pins counted separately, muted - branch detail: Overrides table gains the status column; synced rows offer unbind as the primary action - /changes + (branch-changes): class is the status, not new|override|own - /diff + (diff ...): same hash pairs; the added/removed/modified classification is a view of the same rows (ahead = modified in to, absent in from at matching gens) - merge: upserts ONLY ahead/ahead-new/ diverged paths (diff-based merge TODO closes); conflict report = the diverged set with real bases (conflict-detection TODO closes; blocking resolution stays v2 per merge's recorded policy); on success source and target base_gens advance - promote: after landing, offer unbind of synced pins on the source

RETIRES: - Store.list_overrides (4 call sites: the three /branches renderers + branch-changes; no Nopales package depends on it) - the "main newer" timestamp badge - branches.last_synced (timestamp) – its job is base_gen's, done correctly - diff_branches' scaffolding-table CTEs become historical the day PP_TREE_READS stabilises; during coexistence BOTH the versioned status and the classic diff prim must agree (verifier below) – status is a NEW consumer of the shadow table, not a read-switch of the scaffolding

POSITION IN THE BOOK: this is a tree-time consumer (tree-time.consumers gains a line), sibling to code-history's re-implementation over tree_versions. It does NOT require the tree-time Phase-2 scaffolding read-switch: tree_versions is maintained by the dual-write shadow today, so reading it is additive. Scope is code paths only (b.* / fn-type-route); data rows are branch-free by the one-tree DECISION and have no branch status to compute.

PHASES: S1 migration: ALTER branches ADD base_gen + backfill; fork writes it; merge/promote advance it. Store.branch_status over tree_versions + one equivalence verifier (sample N branches: statuses vs diff_branches head-vs-head where both defined). S2 surfaces re-render: /branches, branch detail, /changes, branch-changes prim, /diff alignment. list_overrides deleted in this phase, not before. S3 merge + promote consume the statuses; conflict report = diverged set; base_gen advancement tested end-to-end (fork -> edit both sides -> merge -> status clean again = git's post-merge state).

> – *agent note:* 2026-08-28: implemented + verified same-day as the plan pass. Migration 024 (branches.base_gen + backfill-to-parent-

current-gen approximation); fork/ensure write it; Store.branch_status (store.ml, one round trip, all three kinds, chain-walk over tree_versions + live-pin EXISTS on the scaffolding tables); classify_status decision table; /branches dirty+synced columns, branch detail status table (unbind hint on synced pins), /changes + (branch-changes) class = status; list_overrides DELETED (4 call sites); merge_branch status-driven (upserts only ahead-new/ahead/diverged; conflict report = the diverged set; base advance post-commit) + head-vs-head fallback for non-parent targets. TWO make-phase findings recorded in the details: (1) HASH DOMAIN - the stored tree_versions.hash column is NOT comparable across write paths (tree-first Tree_store.hash_body compact-JSON digests vs 009-mirror digest(jsonb::text) spaced-canonical digests: identical bodies, different hashes - 020 itself calls the stored hash "a consistency artifact, not content"), so status computes digest((body->'body')::text) AT QUERY TIME, one domain regardless of writer; a global rehash is tree-time scope, and gen-diff has the same latent cross-domain hazard when the two compared gens were written through different paths. (2) MERGE BASE ADVANCE MUST RUN POST-COMMIT - the 017/019 gen-bump triggers are deferred, so reading branch_generations inside the merge tx sees the pre-merge counter; the advance is a separate statement after with_transaction returns. Verified: image/test/branch_status_test (lifecycle: fork base_gen = parent head gen, empty fork clean, ahead-new, diverged, behind, post-promote synced, merge advances base_gen + post-merge synced; identical-pin-synced + unbind-returns-clean) + live smoke on the dev habitat (fork -> define -> ahead-new -> promote -> synced -> redefine -> diverged -> merge reports the conflict by name -> synced). Full dune runtest green; borge drift: none.

[verify] build: dune build @all; test: image/test/branch_status_test.ml – lifecycle: fork sets base_gen = parent head gen; merge advances base_gen; test: statuses: empty fork = clean; own new fn = ahead-new; promote-then-status = synced; parent-only edit = behind; both-sides edit = diverged; identical pin = synced; unbind returns it to clean; test: equivalence: diff_branches reports the diverged fixture as modified head-vs-head, agreeing with branch_status; smoke: S2: /branches renders dirty + synced columns; branch detail status table with unbind hint on synced; (branch-changes) class = status; list_overrides has no callers; smoke: S3: merge upserts only ahead/diverged names (merged 0 rows when all synced); conflict report names the diverged set; base_gen advances post-commit

agent-promote

Agent promotes from its workshop into the parent human's personal

[status: implemented]

promote(source=<parent>/agent, target=<parent>/personal): Selective upsert of function_defs from the agent's workshop into the parent human's personal branch (same mechanism as promote_to_main, different target). The agent's work lands in the human's garden.

Permission: gated by the parent human's allow_agent_promote toggle (users table, default true). The human can revoke it to freeze the agent out of their personal branch; the agent still works in <parent>/agent but cannot promote.

This is the human-in-the-loop gate: the agent builds in its own branch; nothing reaches the shared tree (system/main) or the human's garden until the agent promotes and the human allows it. promote to system/main remains admin-only.

– *agent note:* 2026-08-02: promote_to_personal + allow_agent_promote user toggle + set-allow-agent-promote prim; agent boots parent/agent workshop.

schema-authority

Types in main, branches read against main's schema

[status: partial]

Schema authority is 'main'. Branches cannot change the underlying table shape directly; schema changes land via additive-only migrations applied on boot (see migrations.additive-only), and are visible to all branches immediately on next function lookup.

data_rows has no branch_id; type_defs are stored per-branch but the underlying table shape is shared (see object-model). Branch code that ignores new fields reads a subset without error. Branch code that expects removed fields would fail, but additive-only means removed fields do not occur.

type_defs merge: not yet implemented. Today all data lives in the shared data_rows table; per-type Postgres tables are not created by deftype.

– *agent note:* 2026-08-02 confirm partial: shared data_rows + additive migrations; type_defs merge still not implemented (details admit).

personal-workspace

Boot on empty <user>/personal; seed package defaults only onto system/main

[status: implemented]

MODEL: - system/main = package defaults (inheritance root). Boot seed_stdlib writes libs/*.pp here only, under seed-policy (additive – see below). - <user>/personal = garden (user channel). Empty child of system/main (parent pointer only). Image boots here after seed. User (define) and (route) write personal rows only. - <user>/dev = optional workshop (also empty child). Prefer for product spikes you intend to promote; keep personal for long-lived custom pins. - <parent>/agent = agent user's default workshop. Empty child of system/main (sibling of the parent human's personal). An agent user boots here, not into the parent's personal. The agent works in its own branch and promotes into the parent's personal when the human allows it (see promote). - Inheritance: recursive CTE; child overrides shadow main; unpinned names auto-see main updates.

BOOT ORDER: 1. ensure_branch owner=username name=personal parent=system/main (no code copy) 2. seed_stdlib with store.branch_id = system/main (additive persist – see seed-policy) 3. checkout personal + rehydrate env from CTE 4. refresh ui/nav shell

load-library on CURRENT branch still upserts that branch (intentional pin). On personal/dev that pins the whole package – prefer small overrides or work name-by-name via define.

(checkout "system/main") / (checkout "admin/personal") rehydrate sync; header shows current branch.

unbind

Remove a branch-local binding; reveal shadowed system/main, never delete through

[status: implemented]

– *agent note:* 2026-08-05: implemented (unbind name) in Store.delete_function + session.ml prim. Tested on local dev: unbind branch-local override reveals system/main binding; unbind missing returns "nothing to unbind"; unbind on system/main errors. 160 dune tests green.

[verify] build: dune build; test: dune runtest – unbind cases; test: (unbind name) on a branch-local define removes the branch row; system/main binding revealed; test: (unbind name) on system/main errors (cannot unbind on main); test: (unbind name) with no branch-local row errors (nothing to unbind); test: unbind never deletes another branch or system/main rows

PROBLEM: transient defines accumulate as permanent litter – agent probes, test fns, spike code. Every (define) on a personal branch is a permanent row. There is no way to remove a branch-local binding without deleting the whole branch.

PRIM: (unbind name) Deletes ONLY the current branch's function_defs row for name. After unbind, name resolves via inheritance to whatever system/main (or a parent branch) provides – revealing the shadowed binding, if any.

SEMANTICS: - On <user>/personal or <user>/dev: deletes the (branch_id, name) row from function_defs. The env rehydrates so the name now resolves to the inherited (system/main) binding, or becomes unbound if main has no such name. - On system/main: ERROR. Unbind never deletes a system/main row. (system/main is the inheritance root; removing from it would affect every user.) - If no branch-local row exists for name: ERROR (nothing to unbind). This prevents accidental no-ops and makes the caller explicit. - Never deletes rows from other branches. - Routes (view_bindings) are out of scope for v1; unbind is function_defs only.

INTERACTION WITH PACKAGE PINS: load-library upserts/pins package bindings onto the current branch. (unbind name) on a pinned binding is an unpin – it removes the branch-local override, revealing the system/main package binding. A future (unbind-package pkg) could drop a whole pin; out of scope for v1.

AUTH: admin or the branch owner (consistent with checkout / promote gating). Anonymous sessions cannot unbind.

NON-GOALS: - Unbinding routes (view_bindings) – follow-up. - (unbind-package pkg) bulk unpin – follow-up. - Unbind on system/main (always errors).

package-updates

Authority model: live Postgres Nopales, git kernel + vault, additive seed
[status: implemented]

– *agent note:* 2026-08-02: dual-era authority is operational – seed-policy additive, pp_sync vault, promote path, personal pins survive deploy. Matches AGENTS.md.

==========
DUAL-ERA AUTHORITY (intentional, long-lived) ==========
Destination: stable OCaml core; most product change is live define/promote on the habitat. Until the core is calm, both surfaces exist – but each has one job.

THREE CHANNELS:

1. KERNEL – OCaml binary (HTTP, prims, loader, chrome). Source of truth: git. Update: push ? build ? restart. No branch involved.

2. PACKAGE DEFAULTS – function_defs on system/main. Source of truth while running: Postgres system/main. Daily update path: promote from personal/dev (see promote). Boot seed is ADDITIVE only (see seed-policy): fills missing names from libs/*.pp; never overwrites an existing main row. Explicit reseed is the only git?main clobber.

3. GARDEN / WORKSHOP PINS – rows on personal, dev, or other children. Never written by boot seed. Survive every deploy. Shadow main until unoverride or promote+unoverride.

GIT'S TWO JOBS (do not mix): A. Kernel repo – authoritative for OCaml/migrations. B. Nopales vault – exported snapshots of packages/ branches (backup, bootstrap, clone-to-laptop). Not the daily Nopales editor. See lisp-snapshot.

DATA (data_rows) is never versioned by branch and never wiped by deploy. New package code must tolerate older row shapes or ship an explicit data migrator.

DEFAULT WORK LOOP (product Nopales): work on personal or dev on the ONE habitat (prod) ? dogfood against real shared data ? promote selected names ? system/main ? optional snapshot/export into repo (vault) ? optional unoverride so inheritance is clean Local dev.sh PG is kernel-lab only, not daily Nopales.

UPDATE RULE (after additive seed): new name in libs, absent on main ? appears on seed existing main name ? unchanged by seed personal/dev override ? still shadows main want git body on main ? explicit reseed want garden body on main ? promote

CONSCIOUS UPDATE UX (branch browser; partial today): per name: Use main (unoverride) | Keep | Diff per package: Reset garden pins to main (bulk unoverride) load-library on non-main: warn that it pins the package

Anti-patterns: - boot seed overwriting existing main defs - reseed onto personal/dev - auto-merge main?personal on boot - full copy-on-fork for personal (freezes forever) - treat data_rows as package payload - editing libs/*.pp as the primary product path while also defining the same names live without promote (split brain)

> *[verify] build: dune build image cli; smoke: boot seed does not change body of existing system/main fn; smoke: boot seed inserts a libs name missing from system/main; smoke: personal define survives image restart without pp_sync*

seed-policy

Additive boot seed into system/main; explicit reseed may clobber

[status: implemented]

PROBLEM TODAY: persist_function is INSERT ... ON CONFLICT DO UPDATE. seed_stdlib load-library therefore CLOBBERS every system/main name present in libs/*.pp on every boot. Live promote to main is not durable across deploy.

OPTION A (chosen):

1. ADDITIVE BOOT SEED seed_stdlib still runs on boot, still targets only system/main, still reads PP_LIBS_DIR/<pkg>/lib.pp. Persist path used by seed MUST NOT overwrite: INSERT ... ON CONFLICT (branch_id, name) DO NOTHING or equivalent "insert if absent" helper (Store.persist_function_if_absent / seed mode flag). Missing package files: skip + log (unchanged). Routes/deftype seeded from libs: same additive rule where a natural key exists (branch_id, route|name).

2. EXPLICIT RESEED (git ? main clobber, admin only) Prim: (reseed-package "notes") optional (reseed-package "notes" 'force) same. Behavior: - require admin (same gate as promote to system/*) - read libs/<pkg>/lib.pp via loader - eval/persist onto system/main with UPSERT (full overwrite for names in that file) - does not touch personal/dev rows - rehydrate callers as needed CLI: pp-sync reseed <pkg> (calls the prim) Optional later: pp-sync reseed –all

3. load-library / load-string (interactive) Unchanged intent: write the CURRENT branch with upsert. Still the pin hammer. Not used by boot seed once seed has its own absent-only persist. Warn when current branch is not system/main (package-updates UX; may land with change-set).

4. FRESH DATABASE Additive seed on empty main = full bootstrap from libs/*.pp. No separate first-boot mode required.

5. NON-GOALS - seed writing personal/dev - auto reseed on git push without admin prim - deleting main names absent from libs (additive never removes; cleanup is manual or a future prune tool)

> *[verify] build: dune build image cli; smoke: after promote name to main, restart leaves body intact; smoke: (reseed-package pkg) admin overwrites main from libs; smoke: non-admin reseed-package errors; smoke: reseed-package does not write personal rows*

promote

Graduate garden/workshop code to system/main; optional vault export

[status: implemented]

Promote is the blessed path for product Nopales. Git export is optional vault/checkpoint, not required for main to keep the change across deploys (seed-policy).

A. LIVE MAIN (required for shared defaults) Selective upsert of named function_defs from a source branch (personal/dev/?) ? system/main. Already: Session.promote_to_main, Store.promote_functions, POST /branches/promote (admin only into system/*). Also: (merge src dst) for coarser branch merges; promote remains the selective UI/prim path.

ROUTES TRAVEL WITH THEIR HANDLER: promote MUST also upsert any view_bindings row on the source whose handler names a promoted function (preserving visibility). A promoted handler without its route leaves main serving the old binding – the split-brain footgun this rule exists to kill. Routes whose handler is NOT in the promote set do not travel. promote does not touch type_defs (schema-authority).

B. VAULT EXPORT (optional durability in git) export-package / pp-sync pull writes libs/<pkg>/lib.pp (or snapshot tree – see lisp-snapshot). Operator commits. This does NOT change live main by itself. Useful for backup, laptop clone, and explicit reseed.

HAPPY PATH: edit on personal or dev ? dogfood ? promote selected names ? system/main ? optional unoverride on source (clean inheritance) ? optional pp-sync snapshot/pull + git commit (vault)

SELECTIVE: Ship named functions (ui/nav, notes/save, ?), not the entire garden by default. UI: name multi-select on branch detail (exists); package-group select may come later.

PRIM / CLI (v1 make): keep promote UI + Session.promote_to_main optional Nopales: (promote-to-main "name") or (promote-to-main '("n1" "n2")) on current branch pp-sync does not promote (image policy stays in image)

Policy: - promote/merge into system/*: admin only - merge into own branches: free - data_rows never part of promote - image never git-pushes (no repo credentials)

> *[verify] build: dune build image; smoke: POST /branches/promote copies selected names to system/main; smoke: promoted main body survives restart under additive seed; smoke: non-admin promote to system/main denied; smoke: promote of a handler fn also copies its view_bindings row; smoke: view_bindings whose handler is not promoted stay put*

code-history

Append-only before-image history for code rows, captured by Postgres triggers

[status: implemented]

PROBLEM: Every write to function_defs / type_defs / view_bindings is a destructive INSERT ... ON CONFLICT DO UPDATE. Redefine a function and its old body is unrecoverable unless someone happened to pp-sync snapshot first. Merge and promote clobber the same way. There is no history anywhere in the system.

DESIGN: HISTORY TABLES + TRIGGERS (capture below every write path)

code_history(id bigint GENERATED ALWAYS AS IDENTITY, rel text, – 'function_defs' | 'type_defs' | 'view_bindings' branch_id uuid, name text, – fn/type name or route path body jsonb, – superseded before-image (fn/type body) author text, doc text, package text, op text, – 'UPDATE' | 'DELETE' changed_at timestamptz DEFAULT now()) index on (rel, branch_id, name, changed_at DESC)

One BEFORE UPDATE OR DELETE FOR EACH ROW trigger per live table inserts OLD into code_history. Triggers, not OCaml call-site instrumentation, because every write path converges on these tables: define, merge, promote, reseed, boot seed, and even raw psql. A trigger cannot be bypassed by a new call site.

TRANSACTIONALITY: the trigger runs in the same transaction as the write. A rolled-back merge leaves no history rows; a committed merge leaves one per clobbered row. History is therefore exact, never optimistic.

SEMANTICS: - INSERT fires nothing: first definition has no before-image. Version N of a name = live row plus N-1 code_history entries walking changed_at DESC. - ON CONFLICT DO UPDATE fires the UPDATE trigger for conflicted rows only – merge/promote history is exactly the clobbered set, for free. - INSERT ... ON CONFLICT DO NOTHING (additive seed) writes nothing and records nothing. - op='DELETE' rows are how unoverride/branch-drop remain recoverable.

NOPALES PRIMS (read-only): (code-history "name") – current branch (code-history "name" "owner/branch") ? JSON list, newest first: {rel, op, author, doc, changed_at, body} (code-diff "name" n) – current row vs nth-newest history body (unified-ish text diff) Restore is NOT a prim in v1: read the old body and define it back (that define itself lands in history, so restore-by-redefine is lossless).

SCOPE / NON-GOALS (v1): - CODE ROWS ONLY. data_rows history is a separate later decision (storage commitment; shared table). - No retention pruning; review table size later. - No history UI in v1 beyond the prims; the branch-browser Changes view may surface it later. - tree_nodes mirrors are derived state; history lives on the authoritative tables only.

> *[verify] test: image/test/history_test.ml; build: dune build @all; smoke: redefine a fn on personal; (code-history name) returns the old body; smoke: merge that clobbers target rows records one history row per clobber; smoke: additive boot seed records no history rows; smoke: rolled-back transaction leaves no history rows*

land

pp-sync land: promote + vault snapshot + git commit as one operator step

[status: implemented]

PROBLEM: The blessed loop (work on personal/dev ? promote ? snapshot ? git commit) has manual steps 3-4. Skip them and live main drifts from libs/ silently; pp-sync status can see the drift but nothing runs it.

LAND – the one-command ship path: pp-sync land <pkg> [name ...] [–from owner/branch] performs, in order, from the operator's laptop: 1. CHECKOUT-INDEPENDENT READ: export the named functions (or the whole package when no names given) from the source branch (default: the session's current branch). 2. PROMOTE: call the promote prim for those names (admin gate unchanged; routes travel per promote). 3. SNAPSHOT: re-export the same names from system/main and write libs/<pkg>/lib.pp. 4. COMMIT: git add libs/<pkg>/lib.pp && git commit with message "vault(<pkg>): land <names>". The image never git-pushes and never holds repo credentials; land runs where the repo lives. 5. REPORT: print promoted names, conflicts the promote overwrote (visible via code-history), and the commit SHA.

Failure stops the pipeline at the failed step and reports state (nothing after a failed promote is snapshotted; a failed commit leaves main promoted and the vault dirty, printed clearly).

DRIFT VISIBILITY: pp-sync status gains an exit code: 0 clean, 1 drift. The repo monitor command (README) runs pp-sync status so drift shows up on the dashboard instead of being discovered by accident.

NON-GOALS: - land does not merge branches (promote only) - land does not push to remotes - land does not unoverride the source branch (stays an explicit, separate act) - no daemon; land is operator/agent-invoked

> *[verify] build: dune build cli; smoke: pp-sync land notes ui/nav promotes, snapshots libs/notes/lib.pp, commits; smoke: failed promote (non-admin) leaves vault untouched and reports; smoke: pp-sync status exits 1 when libs/ differs from live main*

lisp-snapshot

Clone habitat Nopales state into the git repo as vault/backup

[status: implemented]

PURPOSE: Postgres is the live Nopales store. The repo must still be able to hold a clone of package/branch state for backup, new-machine bootstrap material, and explicit reseed inputs – without becoming the daily editor.

V1 SURFACES (compose existing export):

1. Package pull (exists) (export-package "notes") ? lib.pp text pp-sync pull <pkg> ? libs/<pkg>/lib.pp pp-sync pull-all ? every discovered pkg Default export reads the SESSION's current branch visibility (CTE). For vault of defaults, checkout system/main first OR pass an explicit branch (v1 make: add optional branch ref).

2. Snapshot command (new CLI) pp-sync snapshot - checkout-aware: export all packages with bindings on the chosen branch - writes libs/<pkg>/lib.pp by default (main vault) pp-sync snapshot –branch system/main pp-sync snapshot –branch admin/personal \ –out backups/personal/ - garden pins land under backups/ not libs/ so bootstrap seed does not treat pins as defaults

3. Image prim (thin) (export-package pkg) already returns text. Optional: (snapshot-packages) ? list of pkg names with own or visible bindings (helper for CLI). No git commit inside the image.

4. Operator habit Before risky reseed or migration: snapshot main (+ personal if desired) and git commit. Cadence backups may be cron + pp-sync snapshot.

LAYOUT CONVENTION: libs/<pkg>/lib.pp bootstrap + main vault (seed input) backups/<ref>/... non-main branch dumps (not seeded)

NON-GOALS v1: - automatic git commit from image or CLI - pg_dump of data_rows as part of pp-sync - encrypting snapshots - bidirectional sync daemon

> *[verify] build: dune build cli; smoke: pp-sync pull notes writes libs/notes/lib.pp; smoke: pp-sync snapshot –branch system/main refreshes libs; smoke: pp-sync snapshot –branch u/personal –out backups/personal does not write libs*

branch-browser-ui

Git-like light /branches browser: list, open, stats, checkout, promote

[status: implemented]

> – *agent note:* 2026-08-02: http_branches.ml ~710 lines – list with own code/overrides, detail, checkout, fork, promote to main + soft lint. Spec "TODAY bare table" is stale.

TODAY: GET /branches is a bare table (owner/name, parent uuid prefix, created). No checkout, stats, detail, or promote.

GOAL: tiny Gitea-ish branch page in classic htmx chrome – browse, open, stats, checkout, later promote – no SPA.

ROUTES: GET /branches GET /branches?ref=owner/name detail POST /branches/checkout ref=? POST /branches/fork from + name POST /branches/merge src + dst (later) POST /branches/promote selective (later)

LIST PAGE: Header strip: On: <current> ? + quick links Table columns: ? | branch | parent | own code | overrides | routes | age | actions own code = COUNT function_defs WHERE branch_id (no CTE). overrides = own names also on parent. actions: Open ? Checkout (disabled if current) Labels: system/main "defaults"; */personal "garden" Create card: fork-from select + new name + Create (full fork for experiments; personal stays empty)

DETAIL PAGE (?ref=): Title, parent link, Checkout, back to list Stats: own fns, overrides, own routes, visible fn count (CTE), last define, authors Sections (htmx partials): Overrides (default for personal) – name, author, updated, new|override, view, diff All own code Routes (own view_bindings) Activity / Changes: branching.change-set (ORDER BY updated_at on own defs + transcript) Diff vs parent v1: two <pre> columns of pp_expr (identical / changed / only-here / only-parent)

CHECKOUT: POST ? Session.checkout_to ? 303 /branches or HX-Redirect. Defines already persisted; no "uncommitted" confirm.

PROMOTE PANEL (detail, admin): package multi-select + name multi-select [ ] Merge into system/main [ ] Mark for export (pp_sync pull list) Never dump whole garden by default.

UPDATES BADGE (package-updates): branching.branch-status supersedes the updated_at badge: status = behind | synced tells accept-vs-keep by CONTENT (behind = main moved, offer accept/unoverride; synced = identical pin, offer unbind).

STORE HELPERS (own-branch, no CTE unless noted): count_functions_on_branch count_routes_on_branch list_own_function_names branch_status (branching.branch-status: clean/ahead-new/ahead/behind/diverged/ synced – replaces the retired list_overrides name-presence join) lookup_function_on_branch (no CTE) delete_function_on_branch (unoverride)

NON-GOALS (light): git SHAs/commits, PR review UI, blame, per-branch data, fancy fork-tree viz

> *[verify] build: dune build; smoke: GET /branches shows current ? and checkout; smoke: POST checkout switches current-branch; smoke: detail lists personal overrides vs main; smoke: detail Changes section lists own defs by updated_at*

change-set

Branch change set / transcript: what changed on this branch

[status: implemented]

> *[verify] build: dune build image; smoke: GET /changes?ref=u/personal lists own fns by updated_at; smoke: (branch-changes) returns own function names + updated_at on current branch; smoke: after define on personal, name appears at top of changes; smoke: change row links to /edit and /bindings detail + parent diff when override*

==========

WHY (Smalltalk change set / method transcript) ==========

Combo pack item #2. After live defines, humans and agents need "what did I change on this garden?" without git. Not a full VCS – a living transcript of own-branch code rows + optional session ring of recent defines.

Compounds with: - image.inspector impact-queue (same define hook) - image.system-browser detail ? link here for overrides - branching.branch-browser-ui detail Activity section - promote / package-updates (know what is dirty)

==========
A. DERIVED CHANGE SET (no new table required v1) ==========
Source of truth already exists: Store.list_own_functions ~branch_id ? (name, author, updated_at) Store.list_own_routes ~branch_id Store.branch_status ~branch_id ? clean/ahead-new/ahead/behind/diverged/ synced per name (branching.branch-status; supersedes the retired list_overrides new|override name-presence classes)

"Changes" for branch B = own function_defs ? own view_bindings on B, sorted by updated_at DESC (activity order). Classify each fn row: - new: no parent row of same name - override: parent has name (optionally note if parent.updated_at > child ? main-newer badge) - route: own view_bindings entries (path ? handler)

Nopales prims (read-only, current branch default): (branch-changes) ? list of dict/JSON strings {name, kind: fn|route, author, updated_at, class: clean|ahead-new|ahead|behind| diverged|synced} (branching.branch-status; was new|override|route – superseded 2026-08-28, content-based now) (branch-changes "owner/name") optional other branch if visible to user (same rules as /branches detail)

==========
B. SESSION TRANSCRIPT (define hook) ==========
Same write path as impact-queue (persist_define / install_function success): append {name, at, branch, author, op: define|route|delete} to session ring (last N=64). Optional; derived list from PG is enough if ring is empty after restart.

Nopales: (change-transcript) ? recent session ops Do not require durable data_rows log in v1.

==========
C. UI SURFACES ==========
1) Branch detail (primary): GET /branches?ref=owner/name&view=changes or default Activity section expanded for personal Table: when | name | class | author | open | diff open ? /bindings?pkg=&fn= or /edit/<name> diff ? existing ?diff= two-column pp_expr

2) Optional GET /changes on current branch (short alias redirecting to /branches?ref=<current>&view=changes)

3) system-browser function detail: if name is own-row, badge "on this branch" + link into Changes highlight

==========
D. AGENT ==========
After a multi-define session, agent can (branch-changes) or read /changes to summarize dirty garden before promote. install_function result may append "changeset: N own fns" lightly – impact text remains primary for smoke routes.

==========
E. NON-GOALS ==========
- Per-edit revision history table (later; updated_at only) - git commits / SHAs / blame - Diff of data_rows (code only) - Cross-user global firehose - Blocking define on "uncommitted" state

==========
F. PHASES ==========
C1: UI Activity/Changes from list_own_* + overrides class C2: (branch-changes) prim + /changes alias C3: session transcript ring on define (shared hook w/ impact) C4: browser detail deep-link + agent one-liner

SUCCESS: on personal after editing ui/nav, Changes shows ui/nav at top as override; diff vs main works; agent can list dirty names without scraping HTML.

ast-nodes

Design: addressable AST nodes as substrate for surgical edits and AI patches

[status: planned]

TODAY: two trees, two models - Branch tree: rows in branches, fork/merge, recursive CTE lookup, unit = whole function - AST tree: JSONB blob in

function_defs.body, in-memory eval walk, no node ids, edit = replace whole body

DESIGN (2026-08-16, ralph loop 19, BORGE-1786925842): Give AST nodes ADDRESSABILITY so tools can patch subexpressions and a genuine THREE-WAY MERGE can be computed, reusing the diff spine already shipped (branching.diff / lisp-interpreter.ast-diff). Kept cheap: identity is a PATH computed on the fly, NOT a materialized table. A materialized nodes table stays OPTIONAL and DEFERRED (see non-goals).

========= 1. NODE ADDRESSING (no table) ========= A node inside a whole-expr body is addressed by a PATH from the root, in the same vocabulary the ast_diff walk already labels its children with: positional: if.test if.then if.else lambda.params lambda.body let.name let.val let.body define.name define.val seq.a seq.b quote.body list: app.fn app.arg[i] prim.arg[i] letrec.binding[NAME] lambda.param[i] Example path: lambda.body.app.arg[1].app.fn.var Identity = (row key: branch_id, name) + path. Pure helpers in lisp/lib make nodes addressable with NO schema change (function bodies stay whole-expr JSONB): select_path : expr -> path -> expr option replace_path : path -> expr -> expr -> expr

========= 2. PATCH REPRESENTATION ========= A two-way diff (base -> target) flattens to a set of atomic path-keyed edits, exactly what Ast_diff.delta already produces labelled by the child paths above: Replace(path, from, to) node at path replaced Insert(path, idx, expr) list-child insert Delete(path, idx) list-child remove The Replaced <from=absent> sentinel in ast_diff already encodes Insert/Delete at list positions. A patch is therefore diff(base,target) PLUS the path vocabulary - no new algorithm, only the missing path->node selector from part 1.

========= 3. THREE-WAY MERGE (base, ours, theirs) the algorithm tree-time (campaign 5) and local-first sync (campaign 8) both reuse ========= ours = diff(base, ours) theirs = diff(base, theirs) Group edits by node path. Disjoint paths compose with no cross-order. A same path edited by BOTH: - identical target -> keep once (both agreed) - different target -> CONFLICT: report path + ours value + theirs value; v1 resolution = keep-ours + report (consistent with branching.merge's report-only-conflict philosophy); v2 may offer 3-way resolution. Apply the merged edits to base -> merged body, then re-validate (ast_hash equality / eval smoke). A merge always has a base: the fork point, branches. last_synced, or a code_history before-image.

========= 4. MATERIALIZED NODES TABLE (optional, deferred) ========= For SURGICAL in-place patching of one huge function (AI rewrites a subexpression without rewriting the whole JSONB), a materialized nodes(id, branch_id, kind, payload, parent_id, position, ...) table pays off - derived/mirrored from the expr on write (like the tree_nodes mirrors), keyed by (branch_id, name, path). DEFERRED: the non-goal below (whole-function propose/edit ships first) says it is not needed yet, and it adds schema + mirror + writer complexity.

========= 5. LAYERING ========= P1 (this substrate): pure path addressing + replace_path + merge3 in lisp/lib, testable with dune runtest lisp (no Postgres). P2: wire into Store.merge_branch - replace the naive full-copy with diff-based merge + a conflict report using merge3 (this is branching.merge's open TODO). P3 (deferred): materialized nodes table for surgical in-place patching.

IMPLEMENTED so far: the diff spine this design consumes (branching.diff + lisp-interpreter.ast-diff) is shipped (module ast_diff, /diff page, (diff from to) prim). This subsection fixes the AST-node addressing + merge3 design those consumers build on; the P1 merge3 module and P2 merge wire-in are the remaining make work (see BORGE-1786925842).

Non-goals for first product cut (unchanged): - Do not block function-editor or ai-authoring tools on this redesign - Whole-function propose/edit ships first - No alpha-equivalence / rename detection in the merge (inherits the diff spine

non-goals)

– *agent note:* 2026-08-16 design pass (ralph loop 19): nodal addressing + three-way merge are now fixed; materialized nodes table deferred. Re-filed issue BORGE-1786925842. 2026-08-02: design-only proposal; function_defs remain whole-body JSONB.

8 borge/lisp-interpreter.borg

pricklypear-lisp-interpreter

Pricklypear book chapter: lisp-interpreter
[status: implemented]

> – *agent note:* 2026-08-02 status reconcile: eval TCO+budget + macros (defmacro/qq/expand) shipped; dune runtest lisp 123 OK; define/defmacro persist synchronous.

lisp-interpreter

Pure interpreter for Nopales (a Scheme-flavored Lisp-1), AST-as-source, primitives layer
[status: implemented]

language-roadmap

Nopales trajectory phases 1-3: code-as-data law, dialect ergonomics, production capabilities
[status: implemented]

> *[verify] smoke: phase exit criteria listed per phase; phases 1-2 and public-route half of 3 are green; test: conformance suite pins phase 1-2 surface*

NORTH STAR Nopales is a small Scheme-family impure functional language for a live multi-user image (humans + agents + Postgres). Not pure FP. Not R7RS-complete. Not a static-typed ML.

STATUS Phase 1 EXIT – symbols + errors-and-locations implemented. Phase 2 EXIT – binding-sugar, match, std-library, guard. Phase 3 PARTIAL EXIT – public Route_gate + package-surface + budgets enforced; broader per-agent tool masks remain additive follow-on (see capability-enforcement). core-freeze contract + conformance suite enforce the seam. Phase 4+ (modules-lite / hygiene / maps): still out of scope until real dogfood pain.

PHASE 1 – HONEST CODE-AS-DATA (done) symbols; errors-and-locations (kinds + parse loc + guard). Exit: 'a vs "a"; symbolic AST heads; structured errors; dune runtest lisp green.

PHASE 2 – PLEASANT DIALECT (done) binding-sugar; match; std-library freeze; guard catch. Exit: define (f x)?; begin multi-body; match on trees; frozen list/string/symbol helpers; guard recovers.

PHASE 3 – PRODUCTION CAPABILITIES (public gate done) effects inference + Route_gate public allowlist; package-surface exports; eval budgets hard leash. Remaining additive: denser agent-session effect masks.

DECISION DEFAULTS (locked) - Impure functional Scheme-family dialect - Dynamic typing + effects + data schemas (not HM types) - Unhygienic macros + gensym (no syntax-case in 1-3) - No call/cc - No in-Nopales fiber/async API (host owns concurrency) - Branches remain the override model; modules-lite = P4+ - JSON/dict prims for records; no VMap required in 1-3

core-freeze

Nopales core 1.0 freeze: the frozen language contract and the slow-change rule that produces long-term stability
[status: implemented]

> *[verify] smoke: core 1.0 frozen-surface list is enumerated and matches the reader, value, special-form, primitive, effect, and error chapters; smoke: a proposed core change is classifiable as additive, deprecate-then-remove, or break against this rule; test: conformance suite exists, is service-free, and runs green on a clean core*

THE CONTRACT. This subsection is the slow-change law for Nopales core. Phases 1-2 of language-roadmap and the public route half of Phase 3 have exited; the frozen-surface list below is the working core 1.0 contract enforced by the conformance suite. Further additive work is allowed; silent meaning changes are not.

FROZEN SURFACE (core 1.0): - Reader surface syntax: s-expressions, quote/quasiquote/ unquote/unquote-splicing shorthand, parse errors with line and column. - Value model: VStr, VInt, VFloat, VBool, VSymbol, VPair, VList, VLambda, VMacro, VPrim, VRef, VNil, and the JSON codec that serializes values/exprs into function_defs. - Special forms: quote, quasiquote, unquote, unquote-splicing, define (incl. function sugar + doc), lambda, if, let, letrec, begin/seq, match, guard, error, defmacro, cond, and, or, apply, list/map|filter|foldl| foldr, gensym, macroexpand*, with-transaction, and the image control forms checkout/fork/merge/route when bound. New special forms may be added; existing meanings do not change in place. - Pure/primitive set: arithmetic, comparison, list, string, symbol, predicate, type-of, whoami, current-author, dict-*, and the std-library freeze table. Optional args with defaults OK; silent return-shape change is a break. - Effect lattice: capability tags, infer, policy_allows, Route_gate public allowlist. Adding a tag is additive; redefining an existing tag's meaning is a core bump. - Error kinds + locations (interp_error_kind, Parse_error line:col, guard catch surface, budget uncatchable).

SLOW-CHANGE RULE. A core change is one of: - ADDITIVE: new prim / special form / effect tag / optional arg with default preserving old behavior. Always allowed. - DEPRECATE-THEN-REMOVE: add new name/behavior, keep old under deprecation, remove only across a named release. - BREAK: only with explicit core version bump (Nopales 2.0) and a migration path for product code.

PRODUCT LAYER IS NOT FROZEN. libs/*, user branches, routes, themes change freely via define/route (OCaml slow, Nopales fast). The freeze is the seam that makes the fast layer safe.

ENFORCEMENT. lisp/test/conformance_test.ml – real Nopales programs with expected values, service-free, in dune runtest. A reddened case does not land until the suite is updated intentionally and the change is classified under this rule. borge drift guards structure; conformance guards semantics.

VERSIONING. Nopales core versioned separately from the Pricklypear framework; coupled only at a major core bump.

FOLLOW-ONS (additive, not freeze blockers): - Broader per-agent effect_mask on every tool prim - symbols phase C (strict string-eq) - denser product-package pure snippets in conformance

conformance

Conformance suite: real Nopales programs with expected eval results, run on every core change as the semantic gate of the freeze

[status: implemented]

> *[verify] test: suite loads and evaluates each program against its expected value with no services; test: a deliberate core change that alters a program's result is caught as a failure; build: dune runtest lisp includes conformance*

WHAT IT IS. A set of real Nopales programs, each paired with the value it must evaluate to, run by the pure interpreter with no services. Tier between OCaml unit tests and HTTP smokes: the LANGUAGE gate of core-freeze.

LOCATION. lisp/test/conformance_test.ml – alcotest cases of the form (name, program, expected-pp-value) plus a few multi-form setup programs. Runs under dune runtest lisp.

CONTENTS (v1 frozen-surface cases): - reader: quote, quasiquote/unquote, lists, strings, bools, string escapes (named, \\ddd byte, \\uXXXX unicode

scalar) - values: VInt VStr VSymbol VBool VNil VList distinctness - special forms: define sugar, lambda, let, if, begin, match, guard, cond, and/or, defmacro/gensym - pure list HOF: list/map list/filter list/foldl list/foldr - errors: unbound kind; guard recovers; budget uncatchable - symbols: 'a vs "a"; car of quoted lambda is symbol Product-package headline cases that need DB/HTTP stay in the smoke tier (libs/verify). Pure kernels of those packages may be added here as pure snippets over time.

RUN MODEL. Service-free pure interpreter only. A reddened case blocks core change land until the suite is updated intentionally and reclassified (additive / deprecate / break per core-freeze).

SCOPE. Pure eval results only. DB prims and routes ? smoke.

ast

The expr and value types

[status: implemented]

type expr = | Var of string | Lit of value | App of expr * expr list | Let of string * expr * expr | Letrec of (string * expr) list * expr | If of expr * expr * expr | Lambda of string list * expr | Prim of string * expr list | Seq of expr * expr | Quote of expr (* data quote; see macros *) | Quasiquote of expr (* macros.quasiquote *) | Unquote of expr | UnquoteSplicing of expr

type value = | VInt of int64 | VFloat of float | VStr of string | VSymbol of string (* see subsection symbols *) | VBool of bool | VNil | VPair of value * value (* cons cells *) | VLambda of string list * expr * env | VMacro of string list * expr * env (* defmacro transformer; params bind to UNEVALUATED arg exprs reified as values via quote_to_value; body returns a value tree that value_to_expr turns back into an expr for re-eval. See macros. *) | VPrim of string (* primitive name *) | VRef of type_name * id (* tagged ref into store *) | VList of value list (* sugar for nested pairs *)

The AST IS the source (homoiconicity). Stored as JSONB in function_defs.body. The reader (s-expr parser) produces expr values; the printer round-trips them. No parser/printer asymmetry.

Closures capture their defining env (lexical scope). VLambda carries env. No dynamic scope.

VRef carries its target type so the interpreter can verify derefs at call time before querying the store.

VALUE ATOMS vs CODE NAMES: At the expr layer, Var s and Lit (VStr s) are distinct. At the value layer, VSymbol holds code names and VStr holds string data (see subsection symbols). Quote / read-string / function-ast trees match Scheme-family code-as-data.

ast-diff

Pure structural diff over expr trees (consumer: branching.diff). Not the surface prim – the pure walker.

[status: implemented]

> – *agent note:* 2026-08-16 ralph loop 19: implemented + verified (lisp/lib/ast_diff.ml, 27/27 ast_diff tests green, full runtest exit 0). Pure module, no I/O, tests with no services (dune runtest lisp). Depends on the frozen expr type (core-freeze) and analyze.ast_hash for the equality fast-path. Semantics authority: branching.diff – this subsection is the module home, not the semantics.
>
> *[verify] build: dune build lisp; test: lisp/test/ast_diff_test.ml – same/modified/replaced over all 11 expr constructors; test: expr_to_json round-trip preserved: diff never mutates, only reads*

Pure walker over the expr type (see ast). No I/O, no Postgres – tests with dune runtest lisp alone, like reader / eval / env.

type delta = | Same | Replaced of { from: expr; to_: expr } | Node of { ctor: string; children: (string * delta) list }

val diff : Ast.expr -> Ast.expr -> delta

Per-ctor recursion (fixed-arity positional for If/Seq/Lambda/Let/Define/Quote; list-LCS for App.args and Letrec.bindings) and non-goals (rename detection, alpha-equivalence, param order) are spec'd in branching.diff – this subsection is the module home, not the semantics authority.

STAKEHOLDER on core-freeze: ast_diff is a structural consumer of every expr constructor. Adding a constructor to expr requires a diff case here (exhaustive match) – borge drift will reddens a missed case, but the freeze contract (see core-freeze) naming a reason the expr type is slow-change now includes this module.

symbols

Distinguish symbols from strings at the value layer (undo v1 collapse)

[status: implemented]

> *[verify] test: quote hello is symbol; quote "hello" is string; not equal; test: value_to_expr round-trip preserves Var vs Lit VStr without ___str___; test: gensym returns VSymbol; test: symbol? string? symbol=? symbol->string string->symbol; test: type-of distinguishes symbol and str; smoke: function-ast / read-string heads are symbols; ui/home still renders*

SHIPPED (phases A + B). Code-as-data trees use VSymbol for names; strings stay VStr. Collapse is REJECTED.

VALUES (quote hello) => VSymbol "hello" (quote "hello") => VStr "hello" (symbol? 'lambda) => #t (string? "lambda") => #t (symbol=? 'a 'a) => #t (car (read-string "(lambda (x) x)")) => symbol lambda

TYPE + PRINT/READ OCaml: | VSymbol of string JSON values: {"sym":"hello"} vs {"str":"hello"} expr JSONB unchanged ({var}/{str} already distinct) – no migration of function_defs bodies. Printer: VSymbol bare; VStr double-quoted. Reader: bare token -> Var; "?" -> Lit VStr.

BRIDGE quote_to_value: Var -> VSymbol; Lit VStr stays VStr; App heads that were Vars become VSymbol heads in VList. value_to_expr: VSymbol -> Var; VStr -> Lit VStr (never Var). reify_expr / macros use quote_to_value (no ___str___ primary). gensym returns VSymbol (optional string prefix).

PRIMITIVES (image prims_pure; registered at boot) symbol? string? symbol=? symbol->string string->symbol type-of -> "symbol" | "str" | ? as-str ACCEPTS VSymbol (HTML/path ergonomics) string-eq: phase-B compat still coerces via as-str/coerce_str so product packages do not mass-break. Prefer symbol=? for AST car walks. Strict string-eq (reject symbols) is deferred cleanup (phase C), not required for this section.

DEFERRED (phase C cleanup – non-blocking) - Remove residual ___str___ unwrap paths once no inflight macros - Strict string-eq (VStr only) - value_to_expr: refuse VStr heads without string->symbol

NON-GOALS - Full interning / eq identity across processes - Keyword type (:foo) - Changing expr JSONB shape

SUCCESS 'a and "a" are different; code-as-data heads are symbols; macros need no ___str___; symbol prims exist; product home and pure lisp tests green. No DB migration.

errors-and-locations

Structured interpreter errors with source locations; catch surface for packages

[status: implemented]

> *[verify] test: parse error includes line:col; test: unbound var error includes name and optional span; test: guard/with-handlers catches User_error and continues; test: guard does not catch Budget_exceeded; smoke: /api/eval error JSON includes kind and loc fields when available*

SHIPPED SURFACE (v1)

Host signal remains OCaml Interp_error. Every common failure has a stable kind via interp_error_kind (snake_case): unbound_var | not_a_function | arity_mismatch | wrong_arg_count | type_mismatch | budget_exceeded | prim_error | parse_error | user_error

type interp_error = | Unbound_var of string | Not_a_function of value | Arity_mismatch of string * int * int | Wrong_arg_count of string * int * int | Type_mismatch of string * value | Budget_exceeded | Prim_error of string * string | Parse_error of string * int * int (* msg, line, col *) | User_error of string

Locations: - Reader_error / Parse_error carry line:col (reader state). - Unbound_var carries the name; optional span on every expr is deferred (not required for v1 catch/API). - interp_error_loc returns Some (line,col) for Parse_error and None otherwise.

/api/eval error JSON (additive fields; .error always present): { ok: false, error: "?", kind: "unbound_var", name: "foo", ; when Unbound_var line: 12, col: 4 } ; when loc known Old clients that only read .error keep working.

CATCH SURFACE – special form guard (not with-handlers): (guard handler-lambda body?) Handler is a 0- or 1-arg lambda. On Interp_error (except Budget_exceeded, which always re-raises), the 1-arg form receives a tagged list: (error <message-str> <kind-symbol>) Nested guard is OK. Handler return value becomes the result of the guard form.

(error msg) | (error kind msg): raises User_error. Kind+msg concatenates as "kind: msg" in the message string; structured kind on the OCaml side remains user_error (v1).

RELATED – image.dnu-stubs (product holes, not catch) doesNotUnderstand-style stub+callers UX reuses unbound_var kind/name fields from this JSON but does not replace guard.

DEFERRED (not blocking implemented) - Full loc = {source; line; col} on every raise site - Optional span field on expr AST - Stack traces as first-class lists - CL-style restarts / with-handlers multi-pred dispatch

NON-GOALS - Catching host bugs / OCaml exceptions unrelated to eval - Full CL condition system

SUCCESS Common eval failures expose kind + message; parse/read paths carry line:col; packages can guard fallible work and render a friendly value without killing the page; budgets remain an uncatchable hard leash by default.

reader

The reader turns source text into AST; the AST is the source of truth (homoiconic, persisted as JSONB); read/print roundtrip fidelity is what makes stored code trustworthy.

[status: implemented]

> *[verify] build: dune build lisp; test: named + \ddd + \uXXXX escapes decode; \uXXXX UTF-8-encodes to 1-4 bytes; test: "\u203e" reads to the single-char overline ?, not literal u203e; test: lone surrogate \uD800..\uDFFF raises Reader_error; test: read/print roundtrip of a string holding ? preserves it (escape_string emits \ddd bytes); test: forgiving fallback: unknown \x still yields literal x; test: conformance pins \uXXXX decode so silent removal reddens the suite*

The reader parses Nopales surface syntax to expr values. Standard s-expressions: (foo bar baz), 'symbol, "string", 123, #t, #f, ().

Surface syntax is just an editor concern: a function stored in Postgres is its AST (JSONB), and the s-expr syntax is one of several possible editors (along with the htmx tree-editor that edits the AST directly).

Special forms recognized at read or eval time (decision: eval time, the reader is generic): (lambda (args) body) (let ((name val)...) body) (letrec ((name val)...) body) (if test then else) (define name expr) (* top-level binding *)

(quote x) (quasiquote x) (* macros; sugar ‘x *) (unquote x) (* macros; sugar ,x *) (unquote-splicing x) (* macros; sugar ,@x *) (defmacro name (params) body) (* macros *) (deftype name (fields ...)) (fork parent child) (merge source target) (app "prim-name" args) (* explicit prim call *)

Reader sugar for macros (in addition to ’x -> (quote x)): ‘x -> (quasiquote x) ,x -> (unquote x) ,@x -> (unquote-splicing x) Comma forms are only meaningful under quasiquote; bare unquote at top-level is a reader-or-eval error.

Comments: ; to end of line.

STRING ESCAPES. Inside a "..." literal the reader recognizes, in order of precedence: \n \t \r \\ \" \’ named single-char escapes \ddd exactly-three-digit DECIMAL byte (OCaml String.escaped form; the vault/export path for non-ASCII and control bytes; n must be ?255) \uXXXX exactly-four-hex-digit UNICODE scalar (see below) \x (any other char) forgiving: literal x, the backslash is dropped – editor over-escapes and paste noise do not hard-fail

\uXXXX UNICODE ESCAPE (additive; closes the "u203e" gap). Four hex digits (0-9 a-f A-F), case-insensitive. The scalar is UTF-8 ENCODED into the byte buffer (1-4 bytes), because values/AST serialize to JSONB and CSS/HTML output expects UTF-8 text, not a raw low byte. - BMP scalar U+0000..U+FFFF except the surrogate range D800..DFFF: encode directly. - Surrogate escape \uD800..\uDFFF: NOT a valid scalar alone ? Reader_error "bad unicode escape \uXXXX". v1 does not combine surrogate pairs; write the actual non-BMP char or use two-step decimal bytes if ever needed. This is a deliberate smallness call, not an oversight. Before this existed, "\u203e" fell through to the forgiving rule and became the literal 4 chars "u203e" – this was the visible menu-caret bug (libs/ui) and the degree-sign bug (libs/weather). Classified ADDITIVE under core-freeze: it only gives meaning to a backslash sequence that previously produced garbage; no existing valid program changes meaning (a prior "\u203e" was already broken).

Docstrings (see define-docstring): optional metadata on a top-level binding. Surface forms the reader already produces as plain AST (no dedicated constructor): (define name expr "doc") (define (name p?) "doc" body?) (define name (lambda (p?) "doc" body?)) The string is not a value binding; eval and the image strip it into function_defs.doc (column already on storage.schema).

eval

The evaluator: env * expr -> value

[status: implemented]

> – *agent note:* 2026-08-02: trampoline TCO, budget steps, pure eval+Prim_call; lisp tests green. define persist no longer Lwt.async.
>
> *[verify] build: dune build lisp; test: dune runtest – lisp eval + TCO cases; smoke: tail self-recursion depth » OCaml stack without overflow; smoke: non-tail recursion still correct (e.g. factorial); smoke: infinite tail loop hits Budget_exceeded, not hang/stack*

The evaluator is PURE. It takes an env and an expr, returns a value or raises an interpreter error. No I/O in the interpreter. All side effects go through Prim calls, which the IMAGE layer wires to actual Postgres/SSH/HTTP side-effects.

Cooperative evaluation: the eval loop is stepped; each Prim invocation yields back to the image’s event loop. This gives per-session budgeting: - A step counter per call (default_limit 100_000) - When exceeded, that ONE call aborts - The session continues - (budget-remaining) reads the active call’s leftover steps (dynamic current_budget) - OCaml prim bodies do not tick; only the call site This prevents "user’s bad function wedges the image" entirely. Scale bugs are fixed by cheaper paths (notes.budget-scale), not by raising the limit.

(define name expr) at top-level adds binding to current session’s env AND persists to store. Edit = redefine (update the row). No versioning at the binding level beyond what branches provide.

Optional docstring (define-docstring): trailing string after the value, or leading string in a multi-body define/lambda, is accepted by eval (not bound as the value) and persisted by the image into function_defs.doc.

Application: evaluate operator + args, apply. Primitives are dispatched by name through a table the IMAGE layer registers at boot. The interpreter knows nothing about Postgres or htmx.

Special forms handled in eval, not reader: lambda, let, letrec, if, define, quote, quasiquote, unquote, unquote-splicing, defmacro, plus higher-order list forms list/map, list/filter, list/foldl (OCaml loops + apply – not recursive Nopales frames). The reader produces App/Variants of these as plain AST (or the dedicated Quote/Quasiquote/Unquote constructors when sugar is used – either representation is fine as long as quote_to_value / expand / pp round-trip).

Macro expansion is part of eval application (and of define/load – see macros.expansion-timing). Eval must call expand before ordinary arg evaluation when the operator resolves to a VMacro.

==========

TAIL-CALL OPTIMIZATION (TCO) ==========

Proper Scheme-style TCO via an explicit trampoline in eval.ml (OCaml does not guarantee TCO on recursive calls).

Model: eval_step returns Done value | Tail (env, expr) eval / eval_force runs a loop: while Tail, continue without growing the OCaml stack.

Tail positions (must bounce, not OCaml-recurse): - if/cond: chosen branch - and/or: last subform (and short-circuit non-tails force) - seq: last form; earlier forms forced - let / letrec: body - lambda application: body after binding args (the App node is always tail in its own frame; nested Apps as arguments are forced first) - macro expansion result: evaluated in tail position - list/map|filter|foldl: stay OCaml loops; closure bodies use eval_force (each element is non-tail relative to the list form)

Non-tail positions force to a value (may use OCaml stack for the force frame only, not for the tail chain inside).

Budget: every step still ticks. Infinite tail loops hit Budget_exceeded – never hang, never exhaust OS stack.

Effects: Prim_call still perform; after return, continue the trampoline. Rim re-entry (with-transaction, apply_lambda) uses the same eval_force entry point.

Not required: full CPS, custom VM, or rest-args frames. Heap env frames still allocate per call (TCO saves stack).

macros

User-defined syntactic macros: defmacro, quasiquote, value<->expr bridge, expand-at-define

[status: implemented]

> – *agent note:* 2026-08-02: VMacro, defmacro, quasiquote/unquote, macroexpand-1/macroexpand, gensym; persist as ___macro___ wrapper; gate tests cover macro hiding create.
>
> *[verify] build: dune build lisp; test: dune runtest – lisp – macro/quasiquote/value_to_expr cases; smoke: (defmacro when (t b) `(if ,t ,b ())) then (when #t 1) => 1; smoke: top-level defmacro persists; reload expands call sites on load*

==========

0. WHY MACROS, WHY NOW ==========

Philosophy parked macros ("can come later"). The habitat is past that: product packages, AI authoring, and agents writing Nopales all want surface sugar without growing the OCaml special-form table forever. Homoiconicity is already real (AST-as-JSONB); macros are the missing half – code that writes code as data, then re-enters eval.

Goals for v1: - Users/agents can define (when / unless / and / or ?) in Nopales packages without OCaml changes - Macro bodies use quasiquote so templates are readable - Expansion is inspectable (macroexpand-1) - Persisted function bodies remain readable source ASTs (macro CALL sites stored; expand on load/define) - No hygiene engine; gensym for accidental capture

Non-goals for v1: - Hygienic macros / syntax-case / syntax-rules - Reader macros / custom dispatch chars - Compiler-style whole-program expand - Separate macro package object type (macros are ordinary bindings of value VMacro on a branch) - Macro-defining macros (allowed if it falls out; not a success criterion) - Changing the Lwt eval ABI

==========

1. SURFACE SYNTAX ==========

(defmacro name (p1 p2 ?) body) - Special form (name not evaluated; params not evaluated) - Binds name in the CURRENT env to a VMacro - Top-level defmacro ALSO persists like define: image layer writes function_defs (or equivalent) with a kind/tag distinguishing macro from lambda so reload reinstalls VMacro, not VLambda. v1 acceptable encoding: store body AST as (defmacro name (params) body) OR body with metadata flag is_macro=true. Prefer a boolean/kind on function_defs if a column already exists for kind; else store the defmacro wrapper AST so load can detect head=defmacro. - Returns the VMacro (or name string) – mirror define's "return the bound value" convention unless image layer already normalizes define returns.

(quote x) / 'x - Unchanged: expr -> value via quote_to_value

(quasiquote template) / `template - Evaluates template structure, interpolating unquotes - Outside any quasiquote, bare unquote is an error

(unquote x) / ,x - Only valid inside quasiquote; evaluates x in the current env and splices the resulting VALUE into the template as a single element

(unquote-splicing x) / ,@x - Only valid inside quasiquote list position - x must evaluate to a VList (or proper list of pairs); elements are spliced into the parent list - Error if used in non-list / atomic template position

(macroexpand-1 form) - Special form OR pure prim: if form is (name . args) and name is bound to VMacro, run ONE expansion step and return the expansion as a value tree (quoted shape). If not a macro call, return form unchanged (as value via quote_to_value). - Does not eval the expansion. (Current impl: evals macro body to produce the value tree; matches inbox language-design note c11-4013 contract for REPL inspection.)

(macroexpand form) - Repeat macroexpand-1 until fixed point or budget tick limit; return final value tree.

(gensym) / (gensym prefix) - Pure prim: returns a fresh symbol name as VStr (e.g. "g$42" or "prefix$42"). Counter is process- local (image or lisp package ref cell). Enough for unhygienic capture avoidance in v1.

==========

2. VALUE <-> EXPR BRIDGE (the hard kernel) ==========

Already exists: quote_to_value : expr -> value Lit v -> v Var s -> VStr s App/special constructors -> nested VList with head symbol strings ("if", "lambda", ?)

REQUIRED for macros: value_to_expr : value -> expr Inverse, best-effort, for trees macros produce.

Macro parameter contract (updated): Macro arguments are bound as self-evaluated literal VALUES (plain VStr for strings, VInt/VFloat/etc. for numbers). No ___str___ tagging at the macro call boundary. The ___str___ emit workaround is deprecated.

Rules (v1): VInt/VFloat/VBool/VNil/VStr that are self-evaluating literals -> Lit v VStr s used in OPERATOR / BINDING / PARAM position of a list tree -> Var s (i.e. when value_to_expr sees VList (VStr head :: args), head becomes Var head unless head is a known self- quoting literal form – see below) VList [] -> Lit VNil (* empty list *) VList (VStr "quote" :: [x]) -> Quote (value_to_expr x) or App(Var "quote", ?) – either OK if eval handles

both VList (h :: t) -> App (value_to_expr h, map value_to_expr t) VPair chain treated like list if proper; improper pair error or dotted App – v1: require proper lists from macros; raise User_error on improper VLambda / VMacro / VPrim / VRef as template leaves: error (cannot reify live closures into source expr)

Symbols (Lisp-1 + VSymbol – see subsection symbols): (quote hello) => VSymbol "hello" (quote "hello") => VStr "hello" Macro args use quote_to_value (symbols for Vars, strings for Lit VStr). Residual ___str___ unwrap is transitional only (phase C cleanup).

Round-trip invariant (tests): For any expr e built from reader surface (no live closures): value_to_expr (quote_to_value e) is alpha-equivalent / pp-equal enough to eval the same for pure programs. Exact AST equality preferred where constructors align.

==========

3. EXPANSION SEMANTICS ==========

A VMacro is (params, body_expr, defining_env).

When applying a macro (name a1 a2 ? an): 1. Do NOT eval a1?an. 2. Reify each ai with quote_to_value -> vi 3. Bind params to vi in a child of defining_env (lexical macro env – captures helpers at defmacro) 4. Eval body in that env -> expansion_value 5. expansion_expr = value_to_expr expansion_value 6. Eval expansion_expr in the ORIGINAL call-site env (not the macro's defining env) – standard Nopales macro call-site evaluation of the expansion.

Recursive expansion: If expansion_expr is itself a macro call, expand again (macroexpand loop) subject to the same Budget.t as eval. Infinite macro recursion => Budget_exceeded.

Shadowing: If a local binding shadows a macro name with a non- macro value, App uses ordinary application. is_special_form still wins over macros for the fixed kernel names (lambda, if, quote, defmacro, ?). defmacro names MUST NOT be allowed to override kernel special forms; define/defmacro of those names errors.

==========

4. EXPANSION TIMING (define / load / REPL) ==========

Two moments matter:

A) Interactive / one-shot eval (REPL, /api/eval): Expand at use (call time), as in ?3. Simple and correct for ad-hoc forms.

B) Top-level (define name body) and image load of function_defs: After reading body AST, run a FULL macroexpand on the body BEFORE storing the evaluated VLambda in the session env. Rationale: - Call sites stay fast (already expanded in the in-memory lambda body) - Effect inference (lisp-interpreter.effects) sees real prims, not macro heads - AI/tools that read env closures see expanded code

Persistence choice (IMPORTANT): Store the SOURCE body AST (with macro call sites), not only the expanded form. function_defs.body = source (what user/agent wrote) On session install / load-library / define: expand(source) -> eval -> VLambda in env Why: tree editor, pp, package export (lib.pp), and AI rewrite tools must show what the author wrote. Expanded-only storage would destroy macro use sites.

Optional later cache column expanded_body – not v1.

defmacro persistence: On load, re-bind VMacro from stored defmacro AST BEFORE expanding other defines that might call it. Install order on a branch: 1. all macros (defmacro forms) 2. then functions (define forms), each expanded against the macro env so far Within a single load batch, dependency order may be imperfect; document that macros should be defined before use in packages. v1 may expand with whatever macros are already in env (seed order / name order). Package seed should list macro files/bindings first when this matters.

==========

5. QUASIQUOTE EVALUATION MODEL ==========

quasiquote is a special form, not a macro on quote.

qq(depth, template): depth starts at 1 when entering (quasiquote ?) - (unquote e) at depth=1 -> eval e - (unquote e) at depth>1 -> rebuild unquote wrapper with qq(depth-1, e) (nested quasiquote support) - (quasiquote e) -> rebuild with qq(depth+1, e) - (unquote-splicing e) at depth=1, list context -> eval e, must be list, splice - atoms / Vars / Lits at any depth -> quote_to_value - lists: map qq over elements; splicing flattens

v1 MUST support single-level quasiquote well; nested quasiquote depth counting is required for correctness of macros-that-write-macros but can be tested lightly.

Reader: ‘ introduces quasiquote of next expr , introduces unquote of next expr ,@ introduces unquote-splicing of next expr Prefer producing App(Var "quasiquote",[e]) etc. so existing App special-form path works; dedicated AST constructors (Quasiquote/Unquote/UnquoteSplicing) are allowed if JSON + pp + quote_to_value are updated in lockstep. Pick ONE representation in implementation and use it consistently (recommend App form for less JSON schema churn; dedicated constructors OK if cleaner).

6. INTERACTION WITH EFFECTS / AI / BRANCHES

Effects (lisp-interpreter.effects): - infer_effects runs on EXPANDED bodies when possible - quote / quasiquote templates contribute no runtime effects except through unquote subexpressions - defmacro body effects are Meta/code-time (top-level define persists via the session layer); the expanded call site carries the real effects - prim_effects: gensym = Pure; macroexpand* = Meta/Pure

AI authoring (ai-authoring): - propose-function may emit defmacro and macro call sites; freeze path stores source AST as today - ast-rewrite tools edit source AST; expansion is re-done on next define/load

Branches: Macros are bindings; they inherit/override via the same function_defs branch visibility as functions. A personal branch can override a system macro.

7. ERRORS

- arity mismatch on macro params (like lambda) - value_to_expr failure -> User_error with context - unquote outside quasiquote - unquote-splicing of non-list - defmacro/define of kernel special-form name - macro expansion budget exceeded - improper list from macro body (v1)

8. IMPLEMENTATION PHASES

Phase 1 – Bridge + quasiquote (no defmacro yet) - value_to_expr + round-trip tests with quote_to_value - reader sugar ‘ , ,@ - eval quasiquote / unquote / unquote-splicing - special_forms catalog entries - gensym prim

Phase 2 – defmacro + call-time expand - VMacro value - defmacro special form - App path: if operator evals to VMacro, expand (note: operator is a Var lookup without evaluating args – for (mac ?) head is Var; do not eval head as function-before-expand in a way that forces args. Pattern: lookup Var name; if VMacro, expand; else existing eval head + eval args + apply.) - macroexpand-1 / macroexpand - tests: when/unless style macros

Phase 3 – define/load expand + persistence - expand body on define before env install of lambdas - image load order: macros first - persist defmacro so reload restores VMacro - package seed: allow macros in libs/*

Phase 4 – Product sugar (optional same PR / follow-up) - stdlib macros: when, unless, and, or, begin~seq alias if desired – only if they do not fight existing prims - UI: show macro badge on /bindings (kind=macro)

9. SUCCESS CRITERIA

- (defmacro when (t b) ‘(if ,t ,b ())) works in REPL - (when #t 42) => 42; (when #f 42) => () - ,@ splices: ‘(a ,@’(b c) d) => (a b c d) as value list - quote/value_to_expr round-trip tests green - defmacro survives image

restart / branch checkout - define of a function using macros expands so effects badges see real prims - dune build lisp + dune runtest lisp pass - No regression to pure-prim Lwt ABI

==========

10. DECISIONS LOCKED BY THIS SPEC ==========

- Name: defmacro (not define-macro) - Hygiene: unhygienic + gensym (no syntax-case) - Expansion: call-time always; ALSO expand-at-define/load for installed lambdas; store SOURCE AST - Symbol/string collapse REJECTED (subsection symbols). Do not build new macros that rely on collapse or ___str___. - Quasiquote is a special form, not a user macro - Kernel special forms cannot be redefined as macros

primitives

Primitives are the boundary between the pure interpreter and the outside world. Post-H1 the core is direct-style: prim_fn = value list -> value (lisp/lib/control.ml), and DB-touching prims are invoked via Control.perform_prim with the rim handler owning I/O – no Lwt.t in the prim ABI. The impure functions the interpreter calls into

[status: implemented]

Primitives live in image/lib/primitives.ml. They are REAL OCaml, typed at the boundary, fast. Anything that touches Postgres, htmx, or the OS is a primitive, never user-Nopales.

CRUD: (create 'type {fields...}) -> VRef (get 'type id) -> record value (update 'type id {fields...}) -> VRef (delete 'type id) -> VNil (select-for-update 'type id) -> record (locked)

Branching: (fork parent child-name) -> branch-id (merge source target) -> status (current-branch) -> branch-id (checkout branch-id) -> VNil (* session switches *) (list-branches) -> VList (diff source target) -> VList of changes

htmx/Routes: (route path fn) (* register route *) (render-html node) (* pure-html node *) (hx-get url) (hx-post url) (* attribute helpers *)

Reflection: (type-of value) -> type-tag

(list-bindings) -> VList

Sessions: (whoami) -> username (current-author) -> username (* for perm checks *)

All primitives that touch data consult the CURRENT-AUTHOR (from the binding being executed) for permission filtering, per multi-user model.

Effect tags for each prim are defined in lisp-interpreter.effects (capability lattice).

effects

Capability effects for Nopales programs: classify pure vs DB vs AI vs publish; infer; gate; display. Separate from OCaml 5 host effects and from Lwt async plumbing.

[status: implemented]

> *[verify] build: dune build lisp image; test: effect inference pure vs db vs ai on sample ASTs; smoke: /bindings shows effect badges; AI propose rejects disallowed effects when policy on*

==========

0. THREE PROBLEMS PEOPLE CONFUSE (read this first) ==========

A) ASYNC / COMPOSITION (mostly DONE) Can a function call (get ...) and use the result? YES today: (define u (get 'note id)) (dict-get u "title") Mechanism: eval : env -> expr -> value Lwt.t Pure prims: register_sync wraps Lwt.return DB/AI prims: return promises directly This is the "async problem" for data-in-Nopales. It is runtime plumbing, not an effect system.

B) CAPABILITY EFFECTS (NOT DONE – this section) What powers does this function need? Pure calc vs read DB vs write DB vs AI vs publish

page. Needed for: UI badges, AI safety, page policy, testing without services, author-runs-as-author story.

C) HOST ALGEBRAIC EFFECTS (OPTIONAL LATER) OCaml 5 Effect.perform / handlers inside the interpreter implementation. Could one day replace some Lwt coloring. Does NOT give Nopales programs effects for free. Guest language still needs B.

Do not block B on C. Do not re-solve A while building B.

==========

1. WHY EFFECTS ==========

Today every lambda looks the same: (lambda (x) (* x x)) ; pure (lambda () (get 'note id)) ; read DB (lambda () (create 'note "{}")) ; write DB (lambda () (propose-function ...)); AI + write code (lambda () (render-html "...")) ; page-ish

The OS cares which is which. Effects make that first-class, inspectable, enforceable.

==========

2. EFFECT LATTICE (capability sets) ==========

Base labels (finite, small):

Pure no capability prims; only pure computation ReadDb get, rows, select-for-update, list-branches, ... WriteDb create, update, update-field, delete, deftype, ... Branch fork, merge, checkout Publish route (and later define-page helpers) Net outbound HTTP (http-get, http-post); identity- gated admin/agent at the prim (image.outbound-http) Ai propose-function / LLM client Html render-html (soft; display intent, not security) Txn body expects with-transaction scope

A function's effect set is a SET of labels, e.g. {ReadDb, Html} {WriteDb, Ai} {}

Ordering for policy (allowlist checks): Pure ? anything ReadDb ? ReadDb?WriteDb (writes imply reads usually) optional sugar: Db = ReadDb?WriteDb

NOTE on (define ...): Top-level define persists code – a code-store write performed by the session layer, NOT an effect tracked in the lattice. Distinguish: - effects OF a function body (what it does when called) - effects OF defining it (session install + persist)

==========

3. PRIM EFFECT TABLE (initial map) ==========

Pure: + - * = < > <= >= not list car cdr cons null? pair? count string-append str type-of dict-get dict-set dict-keys hx-get hx-post ; string tags only

ReadDb: get rows select-for-update list-branches current-branch list-bindings whoami current-author ; session read; treat ReadDb or soft Ambient

WriteDb: create update update-field delete deftype

Branch: fork merge checkout

Publish: route

Html: render-html

Ai: propose-function (Ai usually pairs with WriteDb on code store via define path)

Txn-related: with-transaction (special form) introduces Txn scope select-for-update meaningful only under Txn

Image layer owns the table (primitives live in image/). Nopales package may define the effect datatype only.

==========

4. INFERENCE (syntactic, conservative) ==========

effects(expr) = union over subexpressions + effects of any prim head used in App + effects of known global bindings referenced (lookup function_defs metadata / env annotation)

Rules of thumb: - overapproximate: if unsure, add effect - higher-order unknown fn => Effects.top or {ReadDb,WriteDb,Ai,Publish,Branch} policy knob - lambda body effects = function effects - quote bodies contribute no runtime effects - quasiquote: only unquote / unquote-splicing subexpressions contribute;

template skeleton is Pure - infer on EXPANDED bodies when macros are present (lisp-interpreter.macros); macro heads themselves are not prims

On successful (define name body): store inferred effect set next to function (new column function_defs.effects jsonb OR side table OR derive on the fly from body AST – prefer derive-on-read for v1 to avoid migration, cache later)

v1 implementation preference: derive-on-read from AST + prim table (no schema change) optional cache field later

==========

5. GATES / POLICY (where effects pay rent) ==========

a) UI badges /bindings and editor show: pure | db-read | db-write | ai | page

b) AI propose policy (default) allowed = {Pure, ReadDb, Html} denied = {WriteDb, Branch, Publish, Ai} unless user elevates (tune experimentally; document in product-experience)

c) Route publish policy (optional v1) (route path fn) warns or rejects if fn has Branch/Ai pages should be ReadDb/Html/Pure by default

d) Sandbox eval (future) browser anonymous do-it: Pure only

e) Transactions if body has select-for-update or multi WriteDb, linter suggests with-transaction

==========

6. ASYNC STORY (what is already true) ==========

Solved: - eval returns value Lwt.t - prim_fn = value list -> value Lwt.t - composition of DB reads in Nopales works - with-transaction threads dynamic connection

Not the same as effects: Lwt answers "when / how concurrency is scheduled" Effects answer "what capabilities are required"

Example: (get 'note id) is BOTH async (returns promise through eval) AND ReadDb (capability)

You already need both; only async exists today.

==========

7. RELATION TO OCAML 5 EFFECTS ==========

OCaml 5 algebraic effects MAY later implement host-side intercept for DB/AI inside the interpreter (handlers). That is a runtime rewrite of image/lisp internals.

Explicit non-goals for first effects delivery: - do not replace Lwt in Mirage/httpaf/pgx stack - do not expose Effect.perform to Nopales users - do not require monadic syntax in Nopales

Guest programs keep looking like normal Nopales. Effects are metadata + checks, not new call syntax (unless we add optional declare forms later).

Optional sugar later: (define-pure name body) (define-page path body) Desugar to define + check inferred ? declared.

==========

8. IMPLEMENTATION PHASES ==========

Phase 0 (docs/UI copy): explain Pure vs DB vs AI in /about Phase 1: Effect module + prim -> effect set table Phase 2: infer_effects : expr -> EffectSet.t Phase 3: badges on /bindings + /edit + inspect Phase 4: AI propose allowlist gate (configurable) Phase 5: route publish warnings Phase 6: session capability masks + ENFORCEMENT (see capability-enforcement; language-roadmap Phase 3) Phase 7 (optional research): OCaml effect handlers under eval

NOTE: Phases 1-5 of THIS effects subsection are largely done (table, infer, badges, AI gate). Roadmap Phase 3 is about turning metadata into hard gates on public routes and agent sessions – not redoing inference.

==========

9. DATA SHAPES (sketch) ==========

type effect = | Pure | ReadDb | WriteDb | Branch | Publish | Ai | Html | Txn

type effect_set = effect list (* unique sorted *)

val prim_effects : string -> effect_set val infer : prim_table_meta -> expr -> effect_set val subset : effect_set -> effect_set -> bool val pp : effect_set -> string (* "pure" / "read-db+html" *)

No change to value or eval types required for Phases 1-5.

==========

10. SUCCESS CRITERIA ==========

- User can see whether a function is pure or touches DB/AI - AI-proposed functions can be policy-gated by effects - Pure functions remain testable without Postgres - Async composition remains intact (no regression of Lwt ABI) - Spec/docs stop conflating async with effects

binding-sugar

Define and body ergonomics: function define, begin/multi-body

[status: implemented]

> *[verify] test: (define (f x) (+ x 1)) installs lambda; (f 2) => 3; test: multi-body define evaluates to last form; test: (begin e1 e2 ? en) => en; test: old (define name (lambda ?)) still works; test: define docstring forms coexist (see define-docstring)*

SHIPPED.

FUNCTION DEFINE SUGAR (define (name param?) ["doc"] body body* ?) ? (define name (lambda (param?) (begin body?))) Single body may omit begin. Dotted rest params: out of scope (User_error if "." appears in param list).

Still valid: (define name expr) (define name (lambda ?)) (define name expr "doc")

BEGIN / MULTI-BODY (begin e1 ? en) and (seq e1 ? en) – special forms; value of en; earlier forms for effect. body_of_exprs desugars multi-body define/lambda/match/guard arms to Seq chains.

PRINT function-source pretty-prints stored AST; short-form (define (f x) ?) preference is cosmetic when body is Lambda – optional, not required for this section.

NON-GOALS - Internal define - let function sugar - defmacro (name p?) sugar (follow-up if needed)

Docstrings: define-docstring (orthogonal, implemented).

optional-rest-args

Optional and rest lambda parameters: &optional with defaults, &rest collection. Backward compatible with fixed arity.

[status: implemented]

> – *agent note:* 2026-08-05: implemented &optional (default "") and &rest markers in apply_step. No &optional defaults yet (BORGE-1785965096). 8 new eval tests pass; 136 total green. dune build clean.
>
> *[verify] build: dune build lisp; test: dune runtest – lisp eval optional/rest cases; test: (lambda (a &optional b) b) called with 1 arg: b is unbound/empty; test: (lambda (a &optional b) b) called with 2 args: b is 2nd arg; test: (lambda (&rest args) args) collects all args into a list; test: (lambda (a &rest rest) rest) collects extras after required; test: fixed-arity lambdas still enforce exact arity (backward compat)*

House style stays FIXED ARITY for most image code. This subsection adds two backward-compatible extensions so user code stops reinventing optional/keyword args via empty-string sentinels and opts dicts.

SYNTAX (in the parameter list, after required params): (lambda (a b &optional c) body) – c is optional; if omitted, bound to empty string "". (lambda

(a b &optional (c default)) body) – c is optional; if omitted, bound to default (evaluated in the call env at bind time). (lambda (a b &rest args) body) – args is bound to a VList of all remaining arguments. (lambda (&rest all) body) – all-variadic; all args collected.

&optional and &rest may not both appear. &rest must be the last marker. These are markers (symbols matching the literal strings "&optional" / "&rest"), not params.

DOTTED PAIR NOTATION (a . b) remains UNSUPPORTED at the reader level (parse error). The &rest marker is the only way to collect variadic args. This keeps the reader simple.

ARITY SEMANTICS Required params: must all be supplied. &optional: supplied or fewer – no error; missing ones get their default (or "" if no default form). &rest: absorbs any extra args beyond required+optional. Calling with FEWER than required ? Arity_mismatch (as today). Calling with MORE than required+optional (and no &rest) ? Arity_mismatch (as today).

IMPLEMENTATION NOTES - The Lambda constructor / VLambda carry a param spec richer than string list: required params, optional (name, default expr option) list, rest name option. A flat string list with &optional/&rest markers as sentinels is the minimal change; a typed param_spec is cleaner but larger. - apply_step binds required first (arity check against min_arity), then optional (fill defaults for missing), then rest (collect leftover into VList). - params_of_define_sugar must accept &optional/&rest markers and stop raising on their presence (the current '.' check stays – dotted notation is still rejected). - pp_expr / value_to_expr round-trip must preserve the param list shape so function-source prints correctly.

NON-GOALS - &key keyword args (opts-dict convention stays until a real need proves it; Smalltalk keyword messages are the model). - Dotted-pair (a . b) reader syntax (use &rest). - Optional/rest on macros (follow-up; macros already have their own arity path – add later if needed).

define-docstring

Optional docstring on define; persist to function_defs.doc; (function-doc name)
[status: implemented]

> *[verify] build: dune build && dune runtest; test: (define d1 1 "one") binds 1; (function-doc "d1") => "one"; test: (define (inc x) "add one" (+ x 1)); (inc 2) => 3; function-doc has docstring; test: (define f (lambda (x) "lam" (+ x 1))); function-doc and body without dead string; test: redefine without docstring clears or leaves prior doc per documented rule; test: (function-doc "missing") => (); test: old two-arg define still works; load-library packages without docs; smoke: function_defs.doc round-trips across persist + lookup; smoke: fork/merge copy doc with body*

PURPOSE Make every binding documentable in-language so agents and humans can build a live reference (apropos, /ref, platform-ref notes) without a parallel docs system. Inbox SPEC "define docstring" is the product brief; this subsection is the book authority for the OCaml kernel half. Nopales package doc coverage, /ref, and apropos are follow-on product work once this lands.

SCHEMA (already present – no migration) function_defs.doc text – see storage.schema / migrations/001_branches.sql. Column exists; writers and readers historically ignored it. This work wires it. Do NOT add a second description column.

SURFACE SYNTAX (all optional doc) 1. (define name expr) no docstring; bind eval(expr) 2. (define name expr "doc") bind eval(expr); doc = the string literal 3. (define (name p?) body?) sugar ? lambda; no doc unless (4) 4. (define (name p?) "doc" body body*?) leading string literal in the body list is the docstring and is NOT part of the evaluated body (requires at least one real body form after it; a lone string body is a value-returning thunk, not a docstring) 5. (define name (lambda (p?) "doc" body?)) same leading-string

rule inside lambda bodies when the define is top-level: strip into doc and store/bind the lambda WITHOUT the dead string so function-source stays clean

Docstring MUST be a string literal (Lit VStr / reader "?"). A computed expression in the doc slot is a syntax error (User_error), not silently evaluated.

EVAL (pure lisp/) - Accept forms (1)-(5) without error. - Binding value is unchanged vs pre-docstring define. - Pure env does not store docs (no env metadata in v1). - Prefer one shared helper (e.g. split_define / peel_docstring) used by eval and by the image intercept so sugar and doc rules cannot drift. - value_to_expr / quote of Define need not round-trip the doc string inside the AST (doc is store metadata, not part of expr). Body AST after peel has no doc.

IMAGE PERSIST session eval_one / eval_form define intercept and agent_tools.define_binding: - peel name, body_expr, doc option - eval as today (env bind) - Store.persist_function ? ?doc Redefine rules: - docstring present ? write that string to doc - docstring absent ? set doc NULL (explicit clear). Rationale: edit/save and load-library without docs must not leave stale blurbs from an older body. Packages that care keep the string in source. Anonymous may not persist (unchanged). defmacro: out of scope for v1 docstring slot (no third-arg / leading-string capture); follow-up if needed.

STORE persist_function : t -> name -> body -> author -> ?doc:string option -> unit Lwt.t INSERT/UPDATE sets doc (NULL when None). lookup_function / list paths that feed function-doc must SELECT fd.doc (nullable). fork copy, merge upsert, promote_functions: copy doc with body/author so docs survive branch ops.

PRIMITIVE (function-doc name) ? string | () - name: string (binding name) - If visible function_defs row has non-null non-empty doc ? VStr doc - Else if name is a special form ? that form's summary from special_forms catalog (discoverability) - Else if name is a registered prim with a help blurb ? that blurb when one exists - Else VNil Effect class: ReadDb (store lookup); pure fallbacks after miss are fine inside the same prim. Register next to function-source / function-ast. package-exports kernel/std list should include function-doc once shipped.

SPECIAL-FORMS CATALOG Update define entry arity/examples to show optional docstring forms.

NON-GOALS (this subsection) - /ref page, apropos, nav link, ai/context wiring (product docs layer; build after kernel works) - Mass docstring backfill of libs/*.pp - doc on type_defs or routes - Markdown rendering of docs in OCaml UI (plain text) - Changing function_defs PRIMARY KEY or body JSON shape

SUCCESS - One define with a docstring round-trips through persist and (function-doc ?) - Sugar and lambda leading-string forms agree - Existing libs without docs load unchanged - Agents can document bindings in-language and read them back without scraping function-source comments

match

Pattern match / destructuring for lists and code-as-data trees

[status: implemented]

> *[verify] test: match list pattern binds vars; test: match symbolic head (lambda params body) with VSymbol; test: match fallthrough / else via _; test: no match raises catchable User_error*

SHIPPED special form:

(match scrutinee (pat1 body1?) (pat2 body2?) (_ else-body?))

Patterns (v1): _ wildcard x bind variable lit number / bool / nil / string 'sym quoted symbol (VSymbol; VStr compat) "str" string literal (head p?) list starting with symbolic/string head (list p?) explicit list pattern

Semantics: First matching clause wins. Scrutinee eval once. Bindings lexical in clause body (Env.child). No match => User_error "match: no matching clause" (catchable via guard).

Non-goals v1 (deferred): dotted-tail patterns, (? pred p), and/or patterns, exhaustiveness, record patterns, regexp.

SUCCESS: idiomatic AST walk over read-string / function-ast trees with symbolic heads works without car/cdr chains.

math

Numeric tower beyond the four operations: expt/sqrt/trig/log, numeric predicates, integer division aliases, seeded RNG

[status: implemented]

> *[verify] build: dune build lisp image; test: expt/sqrt/log/exp/sin/cos/tan round-trip on known values (float results); test: (expt 2 10) => 1024 int-in int-out; (expt 2.0 0.5) => 1.414? float; test: number?/integer?/zero?/even?/odd? classify VInt/VFloat/VStr/VNil correctly; test: quotient/remainder match div/mod on ints incl. negative dividends; test: (random n) => 0 ? r < n; (random) => float in [0,1); seeded random deterministic per sequence; test: div-by-zero and domain errors (sqrt of negative, log of ?0) raise catchable User_error; test: conformance_test.ml pins at least one case per new prim*

GAP. Core 1.0 froze the four operations (+ - * div / mod), abs/min/max, floor/round, and parse-int/parse-float – but nothing else. Anything numeric beyond grade-school arithmetic currently has to shell out to float-of-string hacks or OCaml. This subsection is the book authority for closing that gap. Classified ADDITIVE under core-freeze.

NEW PRIMS (all pure, all in pure/prims_pure.ml (the shared pure library), registered in primitives.ml, added to the Pure list in lisp/lib/effect.ml; note the Pure list today omits "/" even though div is listed – fix that omission in the same pass so alias pairs (div /) and (quotient remainder) stay classified identically)

Powers / roots / transcendental (float semantics; int-int expt with non-negative exponent returns VInt): (expt base n) int-in/int-out when both int and n ? 0 (Int64 overflow wraps like Int64.mul; documented, no bignum in v1); else float (sqrt x) float; User_error on x < 0 (exp x) (log x) float; log: User_error on x ? 0 (log x b) optional base arg ? (logb x) = log x / log b (sin x) (cos x) (tan x) float, radians (asin x) (acos x) (atan x) float; asin/acos User_error outside [-1,1] (atan y x) two-arg form ? atan2 when given 2 args pi bound as a VALUE (VFloat Float.pi) in the initial env, not a zero-arg prim – agents write pi, not (pi)

Predicates (return VBool; missing core gap): (number? v) VInt | VFloat (integer? v) VInt only; VFloat with integral value returns #f (v1 rule: tag-based, not value-based – keeps it cheap and honest) (zero? n) (positive? n) (negative? n) (even? n) (odd? n) integers only; User_error on float with non-integral value

Integer division aliases (Scheme names, delegate to the existing div/mod int paths – no new semantics): (quotient a b) ? int div; User_error on float args or 0 (remainder a b) ? Int64.rem; User_error on float args or 0

Randomness: (random n) VInt in [0,n) for VInt n > 0; VFloat in [0.,1.) for zero args (random-seed s) reseeds the image PRNG (Random.init with VInt-derived seed); returns VNil Effect class: Pure – Nopales-visible nondeterminism, but touches no capability rim; same class as now/now-ms. One PRNG state per image process is fine for v1 (documented; per-session streams are a non-goal).

EFFECT CLASSIFICATION All new prims are Pure. Quotient/remainder/classification aliases must classify identically to the prim they wrap (div / mod) – alias drift

in the Pure list is a drift failure mode; the conformance suite should catch a prim that infers non-Pure.

ERROR RULES (uniform) - Wrong arity / non-numeric arg ? User_error naming prim - Domain errors (sqrt/log/asin/acos, div-by-zero) ? catchable User_error, never VNil, never NaN leak: prims CHECK before calling the OCaml float op - integer? on VFloat 3.0 ? #f (tag rule above)

NON-GOALS (v1) - Rationals / exact arithmetic tower - Bignums (Int64 wraps; documented) - Complex numbers - (gcd a b) (lcm a b) – useful but trivially writable in Nopales once quotient/remainder exist; candidates for libs/std, not kernel prims - Per-session RNG streams

SUCCESS: agents and product libs can do real math (interest, FSRS scheduling, geometry, statistics) without leaving the language; conformance suite pins every new name so silent removal reddens the build.

std-library

Blessed std list/string helpers: freeze surface for packages and agents

[status: implemented]

> *[verify] test: conformance covers list/map filter foldl foldr; test: symbol and string prims present; smoke: load-library std exports list helpers; idempotent*

RULES 1. FROZEN SET below – signatures must not change in place; bugfixes OK; new behavior needs a new name. 2. Hot loops: OCaml special forms / prims; Nopales std wraps. 3. New std helpers require a conformance or verify case.

FROZEN SET (kernel + image prims + libs/std aliases)

Lists (kernel special forms – OCaml loops + apply): list/map list/filter list/foldl list/foldr Lists (prims): list car cdr cons null? pair? reverse append count Strings (prims): string-append string-join string-length substring string-eq string-contains? string-trim html-escape as-str str Symbols (prims): symbol? string? symbol=? symbol->string string->symbol Misc: not type-of

libs/std also exports ergonomic aliases map/filter/foldl/ foldr and html/* builders – html/* may evolve faster than this kernel freeze; list HOF names above are frozen.

SUCCESS: conformance + dialect tests pin list HOF and symbol/string prims; silent renames redden the suite.

capability-enforcement

Hard gates: public routes and agent sessions obey effect allowlists

[status: implemented]

> *[verify] test: pure and read-db public handlers allowed; test: write-db / branch / net public handlers denied; test: unknown and non-function handlers fail-closed; test: macro-expanded write is denied after expand; smoke: (route ? 'public) refuses over-powered handlers at bind*

SHIPPED (public-route gate). Builds on effects inference.

PUBLIC ROUTES Route_gate.check_public_handler ~env handler: infer effects of the named handler from the in-memory env (macroexpand first). Allowlist default: Pure | ReadDb | Html WriteDb requires PP_PUBLIC_ALLOW_WRITE=1 opt-in. Branch / Ai / Net / unknown ? deny (fail-closed). Session.route bind calls the gate when visibility=public; over-powered handlers are refused at bind (kept private).

AGENT / AI AI propose-function remains policy-gated on the same effect subset helpers. Per-session agent effect_mask for every tool prim is a follow-on tightening (not required to close this section's public-route gate).

BUDGET Eval step budget is a hard leash (Budget_exceeded), uncatchable by default via guard – part of the same production-leash story.

AUTH Orthogonal to is_admin: admin private routes full power; public publish still PUBLIC_ALLOW.

NON-GOALS - Full setuid / run-as-author lattice - Postgres RLS as effects substitute - Required user-authored effect declarations

SUCCESS: sloppy public handlers cannot fork branches or write the store without opt-in; pure unit gate tests green.

package-surface

Blessed package exports and stability rules for system/main

[status: implemented]

– *agent note:* agent plan 2026-08-02 – Phase 1 design settled with roerick. Resolves most of BORGE-1785211142 item a; multi-file libs issue item b stays deferred. Design calls settled in chat:

SETTLED DESIGN CALLS 1. Export names are FULL names like todo/add, not bare auto-prefixed. 2. Registry storage = new branch-lensed tree family b.branch.pkg.name one-tree.tree-model PATH GRAMMAR updated with a package_registry scaffolding table mirroring it, exactly the function_defs pattern table = runtime truth until PP_TREE_READS/WRITES cutover; forward-only mirror triggers. Inherits parent-to-child like function_defs – per-user enable/disable falls out of the branch model for free. 3. std stays ALWAYS enabled – hard-protected; not a registry row. package-exports std keeps serving kernel_std_exports until the std-library freeze lands; do not widen that list in passing. 4. Routes / deftype / macros are OUT of the export list for v1 functions only. 5. Personal branches may still shadow exported names; documented, not prevented.

DISABLE SEMANTICS = HIDE, NOT DELETE. package-disable writes enabled=false on the current branch and re-runs rehydrate; rows stay in Postgres, they just do not load into the session env. Boot seed is automatically safe: seed is additive fills MISSING names and disabled rows still exist, so seeding a disabled package is a no-op. Re-enable flips the bit back; no re-seed.

MVP PRIM SURFACE packages – registry rows: name, enabled, – exports, source header-or-heuristic package-enable workout – enabled=true on current branch, – rehydrate package-disable workout – enabled=false, rehydrate. – std rejected with a clear error. package-exports pkg – resolution order: declared header – set, then kernel_std_exports for – std and kernel, else shallow heuristic

IMPLEMENTATION PLAN touchpoints verified 2026-08-02 1. migrations/011_package_registry.sql – package_registry fields branch_id, name, enabled bool default true, exports jsonb, author, updated_at; PK branch_id+name; plus forward-only mirror trigger copying 009_tree.sql tree_mirror_function_defs pattern pp.tree_mirror guard, CONSTRAINT TRIGGER DEFERRABLE. Forward-only is correct: 009 has NO reverse trigger; runtime truth stays in the table. Also ALTER TABLE function_defs ADD COLUMN package text NULL provenance stamp. 2. tree_store.ml – pkg_path constructor b.uuid.pkg.name via uuid_label + enc_label, mirrors tree_uuid_label in SQL. 3. loader.ml / session.ml – recognize a leading package NAME export ... header form in load-string; do NOT eval it as a define. Upsert the registry row enabled preserved on re-load; exports replaced. While loading that file, stamp persist_function calls with package=NAME session-local current-package string option threaded through eval_one / eval_form persist_define; cleared at end of

load. 4. session.ml rehydrate/load_defs – after loading the registry for the branch chain same recursive-CTE override walk as list_function_names_for_load, first-hit-wins depth ASC, skip defines whose package is disabled on this branch. Untagged defines package IS NULL always load. Routes whose handler belongs to a disabled package are filtered in load_defs route pass too handler package via function_defs.package. 5. agent_tools.ml / session.ml prims – packages, package-enable, package-disable new; package-exports resolution order change; describe prefers declared exports when present. 6. Seed headers: libs/std/lib.pp exports = kernel_std_exports list exactly, libs/ui/lib.pp, libs/layout/lib.pp; todo as the app example. 7. export-package round-trips the package header form into vault text; pp-sync snapshot includes it.

EXPLICIT NON-GOALS FOR PHASE 1 unchanged from details above: sealing, import forms, multi-file libs, requires graph, promote filter, call-site lint. Those are Phase 2/3.

VERIFY maps to the smoke lines on this subsection - package-disable todo then todo/list -> unbound error; rows still in function_defs; package-enable todo restores. - Disabled on admin/personal does not affect system/main. - package-exports todo returns the declared header set, not the shallow heuristic, after seeding the header. - Boot with a package disabled on system/main: seed does NOT re-enable it. - borge drift clean; dune build and dune runtest.

[verify] smoke: export-package or package-bindings lists public names for std/ui; smoke: docs or /bindings marks public vs internal

ROADMAP: Phase 3 (ecosystem law, light).

========== PROBLEM ==========
system/main packages are de facto public API for all gardens. No export list ? agents depend on internals; renames break personal branches silently.

========== v1 RULES (no heavy module system) ==========
1. Each libs/<pkg>/lib.pp MAY start with a declaration: (package pkg-name (export name1 name2 ?)) If absent, all defines are public (status quo). If present, non-exported names are "internal": still callable (Lisp-1) but documented as unstable; optional lint/warn on other packages referencing them.

2. Stability tiers: kernel prims – strongest freeze (with std-library) exported package – prefer compat; rename = new name internal – may change any deploy personal branch – user owns breakage

3. Promote discipline (existing branching.promote): only exported names should be promoted to main without explicit force.

4. Agent seeds: prefer exported names only.

========== NON-GOALS ==========
- Import forms / separate namespaces per file - Version numbers in-package (git/branch is version) - Sealing that makes internal uncallable (too hostile for a Lisp OS v1)

SUCCESS: std + ui + layout have export lists; concepts doc explains public vs internal; agents stop depending on clearly internal helpers by default.

function-observability

Inspect functions: recursion/tail highlight, step counts, DB cost, big-O heuristic, on-demand LLM analysis, inside-out peel

[status: implemented]

[verify] build: dune build lisp image; test: dune runtest – recursion / complexity / explain / eval step attribution; smoke: GET /binding/<recursive-fn> marks self-ref and tail vs non-tail sites; smoke: GET /binding/<fn> shows last-run steps / prim_calls / db_hits when stats exist; smoke: GET /binding/<fn> shows free big-O badge or honest ?; smoke: POST /api/analyze/<fn> returns LLM estimate fragment; cache by AST sha1; smoke: (analyze 'fn) and (explain 'fn) prims return structured results

THESIS

The OS already stores every function as an AST and runs it through a stepped evaluator. Function observability makes that inspectable on /binding and /bindings without inventing a separate profiler product.

Split by cost: FREE / pure sexp – recursion, tail position, big-O heuristic, inside-out peel structure CHEAP / eval hook – step counts, prim calls, DB hits, live DB timing into function_stat ON DEMAND / LLM – (analyze 'fn) complexity + optional per-layer prose glosses

ARCHITECTURE

lisp/ stays pure (yojson only). Static analysis modules live there and are alcotest-tested with no services: recursion.ml – self-refs + tail context complexity.ml – heuristic big-O classifier explain.ml – mechanical innermost?out peel

image/ owns HTML, store, LLM: ast_html.ml – Pure_html AST renderer with classes db_cost.ml – static DB-prim cost tiers + optional EXPLAIN analyze.ml – (analyze 'fn) + cache write http_analyze.ml – POST /api/analyze/:name htmx fragment

Instrumentation seam is the existing eval budget record and current_budget dynamic binding (eval.ml). Extend budget with current_fn, prim_calls, db_hits, fn_step_counts; expose last_budget after top-level eval_string for session persist.

Analysis results dogfood data_rows: function_stat – last/recent measured runs function_analysis – LLM complexity cache keyed by sha1(pp_expr body); edit invalidates

PHASE 1 – RECURSION + TAIL HIGHLIGHT

Recursion.analyze_self ~fn_name expr: is_recursive, tail_recursive, self_ref_sites, mutual_refs (names only; cycles from call_graph). Tail context MUST mirror the trampoline (eval TCO): If then/else Tail; test Non_tail Seq last Tail; earlier Non_tail Let/Letrec body Tail; bindings Non_tail App in Tail context is the tail call; args Non_tail Lambda body is a new frame (Non_tail of the caller) call_graph.mutual_cycles on a snapshot for SCCs. ast_html.pp_expr_html emits spans: ast-self-ref, ast-tail, ast-non-tail, ast-mutual Wire show_binding_page, list_bindings code pane, inspect_binding_page. CSS in chrome style block.

PHASE 2 – STEP COUNTER + ATTRIBUTION

Every eval_step tick attributes to budget.current_fn. apply of named VLambda sets current_fn; non-tail eval restores previous; trampoline tail keeps new name. Prim path increments prim_calls; CRUD wrappers in prims_db increment db_hits (and later timing). After route/api eval, session may upsert function_stat rows (fn, steps, prim_calls, db_hits, when). /binding shows "last run: N steps, M prims, K DB hits".

PHASE 3 – DB COST

Closed set of DB prims ? static tier badges: get/find-row Index_seek; create/update/delete Constant; rows Seq_scan; find-rows/find-text Linear. Optional lazy EXPLAIN on demand (not every page load). Live tier: wrap store calls with wall timing into function_stat.db_time_ms when clock precision allows.

==========
PHASE 4 – HEURISTIC BIG-O ==========
Complexity.classify : expr -> O_constant | O_log_n | O_linear | O_n_log_n | O_quadratic | O_exponential | Unknown Patterns (honest Unknown default): cdr-self-recursion / list/map|filter|foldl ? O(n) two recursive halves ? O(n log n) fib-style multi self-call (- n 1)/(- n 2) ? O(2^n) rows inside map / nested maps ? O(n?) no recursion/loops/DB list forms ? O(1) Free badge on /binding next to effects. Optional later: empirical curve-fit via (bench 'fn sizes) + step counts.

==========
PHASE 5 – LLM ANALYZE ON DEMAND ==========
(analyze 'fn) prim + POST /api/analyze/:name (private). Reuse llm_client; prefer per-user key (auth.user-llm-keys) then env LLM_API_KEY. Structured JSON: {complexity, confidence, rationale, notes} Cache data_rows function_analysis by sha1(pp_expr). htmx button on /binding swaps #analyze-result. Always label "LLM estimate (model, when)". Cross-check against function_stat steps when present. No auto-call on page load.

==========
PHASE 6 – INSIDE-OUT EXPLAINER ==========
Explain.peel : expr -> layer list (innermost first by max depth; siblings left-to-right). Annotate with prim name/effects, self-ref, tail, complexity when known. (explain 'fn) returns layers as readable structure. UI: collapsible explain-layer blocks on /binding. Optional LLM prose gloss per layer, cache by sexp hash; opt-in only (cost scales with depth).

==========
SHIP ORDER ==========
1, 2, 4 independent (can parallelize). 3 after 2. 5 after 2 (+ benefits from 4). 6 after 1+4; LLM gloss optional after 5.

==========
NON-GOALS ==========
- Claiming undecidable static big-O as ground truth - EXPLAIN ANALYZE on every DB prim call - Auto LLM spend on every /binding view - Full coverage-guided test selection (see image.inspector impact queue; related but separate) - Custom VM / full CPS just for profiling

SUCCESS: a human or agent opening /binding/foo sees structure (recursion/tail), free cost guess (big-O + DB tier), measured last run when available, and can click for LLM analysis or peel without leaving the browser.

lazy-env-thunks

VThunk: memoized lazy bindings; env LOAD stores recipes, first reference cooks them; explicit (delay)/(force) surface

[status: implemented]

> *[verify] build: dune build lisp; test: dune runtest lisp: thunk forces once, memoizes value AND failure, cyclic force raises, delay/force round-trip; smoke: (force (delay (+ 1 2))) = 3; forcing twice runs body once*

MOTIVATION (measured on prod 2026-08-21) Session.load_defs re-EVALUATED every function_defs body on every rehydrate: ~4013 defs on admin/personal took 60-120s under the global request mutex whenever HTTP identity flipped (one shared session, anonymous public traffic interleaving with authed agent traffic). But ~98% of defs are lambdas nobody touches between rebuilds: pure define is ~1us; the cost was STRICTNESS AT THE WRONG BOUNDARY, not interpreter speed and not per-def Postgres round trips (the load query is one recursive CTE). Habitat note spec/lazy-thunks (2026-08-20) already argued the general shape: the value is in MEMOIZATION at an EXPLICIT boundary, not pervasive call-by-need.

KERNEL New value constructor in lisp/lib/ast.ml:

VThunk of thunk_cell ref thunk_cell = Unforced of thunk_payload | Forcing | Forced of value | Failed of exn thunk_payload = { body : expr; def_env : env; force : env -> expr -> value }

The payload CARRIES ITS OWN EVALUATOR so the pure kernel stays I/O-free while the image can force under its prim rim (DB prims inside a forced body work) and under the current eval budget. Forcing MEMOIZES on all outcomes: Forced replays the value; Failed replays the exception (a def that errors at first touch does not re-tax every later touch); Forcing detects self-reference cycles and raises Interp_error instead of diverging.

SINGLE OBSERVATION POINT Env.lookup is the one auto-force site. A VThunk never escapes into user values through a Var reference; the language stays strict everywhere else. Direct OCaml lookups (route handler resolution, ui shell) get the same semantics for free. Existing code never sees VThunk except via fold/list-bindings (renders <thunk>).

USER SURFACE (delay EXPR) -> VThunk; EXPR not evaluated (force X) -> forces X if a thunk, else returns X (define ...) stays EAGER: laziness is a property of env loading and explicit delay, never of define. Side-effect order of ordinary code is unchanged.

NON-GOALS - call-by-need language semantics (rejected in spec/lazy-thunks: side-effect order + budget attribution) - transparent forcing at truthiness/printing observation points (only Var forces; decide more after dogfooding) - cross-session or persistent thunk cache (Design B of the note – tree pending-state – remains a separate item)

9 borge/agent.borg

pricklypear-agent

Pricklypear book chapter: agent – GLOCHID, the local-first agent harness: the Nopales-native coding-agent PRODUCT. A local-resident habitat client: one process, one screen, working its own forked branch of the one tree, syncing up, offline-tolerant, with installable browsers. Links remote-eval as its capability/library; shares pricklypear-lisp + llm with the image.

[status: planned]

– *agent note:* 2026-12 ALIGNMENT PASS (product vs capability, the line the code was reaching for). HISTORY: the agent was born 2026-08-03 as a hermetic pi-clone spike ('no Postgres, no branches, no auth'); remote-eval + pp-remote arrived 2026-08-14 as the SAME prim seam with the rim handler swapped to an HTTP proxy, explicitly 'NOT a new product – a mode of the agent host.' The code never converged: agent/ stayed hermetic-local, remote/ grew a second product surface (a chat), and the two forked surfaces/t-records/serve-functions are SYMPTOMS of a missing noun, not independent designs. This pass redraws the line the spec never drew and retires the 2026-08-03 framing. ALIGNMENT: (1) the AGENT is one PRODUCT – a local-resident coding agent, chat + installable browsers (file browser, AST browser, data browser), one process you launch. It is a HABITAT CLIENT BY DEFAULT, not a hermetic spike: each run forks its own branch (lens-<device>), syncs the AST + data down, and works against that LOCAL LENS as the working source – edits are local-first, pushed up via sync, offline-tolerant up to a surfaced merge (local-first.sync-conflicts). The image is the durable store + merge authority, NOT a live read target. (2) REMOTE-EVAL is the CAPABILITY/LIBRARY behind that – sync the AST/data down, eval locally, proxy out-of-working-set prims up to the image, three-way merge on reconnect – NO surface, no chat. pp-remote shrinks back to this library + a minimal /eval harness; the chat surface I just added to remote/ MOVES to the agent (one surface file, one set of chat/* templates, one serve). (3) THE BOUNDARY: agent owns the surface + installable browsers + the coding-agent tool set (read/bash/file-browser over the operator's laptop); remote-eval owns the rim, the lazy env, the def-cache, the sync, the stepping, the wire. The agent never reimplements eval; remote-eval never owns a screen. (4) llm/ (loop+provider+tools) stays shared – it sits ABOVE both: the agent supplies a Loop.host over the local-first rim; a future debugger/test-harness links the same loop over its own host. WHAT THIS PASS DOES NOT DO: restatus the implementation subsections or touch code – this redraws the POSITIONING line only; a make pass retires the agent binary's hermetic path, collapses the duplicated surfaces into one on the agent, and shrinks remote/ to the library. OPEN QUESTIONS the make pass must settle, not this pass: (a) sync cadence – per-write sync is wrong (an LLM making 20 quick edits is 20 merge rounds + 20 merge-bases); a sync round is a coherent UNIT (the turn, or an explicit flush), debounced – decide in local-first.sync. (b) fork garbage collection – every device forks lens-<device>; dead devices leave stale branches. (c) two planes one screen – chat-agent bash edits the operator's LAPTOP repo (the OCaml); Nopales surface edits go to the LENS -> image. Same screen, two planes; name it so it is a feature, not a confusion. The 'agent requires a reachable habitat' call is taken here: offline is DEGRADED working-set-only, not a

first-class mode – the lens makes a flaky link survivable; 'agent with no image, ever' is no longer a product target (retires the 2026-08-03 promise).

– *agent note:* 2026-08-03 chapter created for the pi-clone spike. Positioning: sibling consumer of pricklypear-lisp (like cli/), NOT part of the image product. No Postgres, no branches, no auth. If it graduates into the product later that is a plan-phase spec edit.

– *agent note:* 2026-08-14 v0.0 spike landed: rim moved to Control.run_with_rim (image Control_rim is now a thin alias), Eval.read_eval_all_direct added, agent/ package with stdin REPL + mock provider + read/bash builtins + on/register-tool/register-command + tool_call-block path. Provider is OpenAI-compatible chat completions only (synthetic.new + any gateway, Anthropic via its compat endpoint) – no native Anthropic path; image llm_client.ml is the curl cautionary tale we avoid. agent/ tests 5/5 (incl. provider SSE reconstruction), full workspace green. Known gaps: SSE streaming now lands text deltas live (Openai.complete streams requests with stream:true; text deltas dispatch via on_delta as they decode) but tool-call stream fragments are RECONSTRUCTED into a full assistant message (not streamed live as tool-call deltas) – that reconstruction runs through the shared parse_reply so XML/GLM fallback and history shape are preserved; http_ui.ml landed: HTML primary surface (chat page + inline SSE client), code browser (read-only file tree + file view), –serve/–open wired in main.ml. Chat streams via true incremental SSE (producer-fiber + drain queue, mirroring image http_agent.ml mp/sse pattern). Gluten_eio deadlock avoided by forking handler work off the connection fiber. Code browser has canonical-path traversal guard. All surfaces smokes pass (chat page, SSE deltas, tree list, file render, traversal 403, piped-turn regression).

– *agent note:* 2026-08-14 SURFACE REFACTOR DESIGN (decided, plan-mode): the agent UI moves off SSE+vanilla-JS to Nopales-authored htmx fragments + multipart streaming, so the surface is a loadable Nopales layer both the agent AND the image share. Decision thread: (1) soup/* tree prims are DB-free – lift them from image/lib/prims_hyper.ml into the shared pure-prims layer (pure/) so both hosts register the same tree prims; (2) route/lookup + route/dispatch are THE HOST SEAM (hypermedia-harness.request-runner) – identical Nopales signatures, host-local backing (image Session.t Postgres routes vs agent Runtime.t lens routes); (3) LLM use is always-API (no local inference), so the main habitat stays the corpus source of truth; the agent evaluates against a LOCAL-FIRST LENS (local-first.borg), not a hermetic embedded corpus – edits sync up per local-first.lens-model. This revises the 2026-08-03 positioning which said 'no Postgres, no branches, no object store' and made the corpus embeddable. Streaming stays OCAML (provider SSE -> deltas -> per-part (html,target,swap) assembly -> multipart frame + flush), with Nopales owning the fragment templates; soup/apply-parts! models a consumed turn as data for libs/hyper. Phasing (read-only lens vs write-capable lens in the first cut) was left OPEN in discussion – record it in local-first.phasing when decided.

– *agent note:* 2026-12 CAMPAIGN 6.0 PLAN PASS (agent surfaces / route table spec): revealed the agent-route-table + surfaces implementation was ALREADY COMPLETE in agent/ (built

since the 2026-08 design). Reconciled both stanzas' verify stanzas + details to the implemented reality WITHOUT a status flip (per the plan-pass/make division of labour – 6.1 make flips them planned ? implemented). Verified live: agent_test 13/13 green; smoke_agent_surface.sh 14/14 PASS; piped-turn '–once' + '-p' pipe mode both work. agent-route-table = route / route/lookup / route/dispatch + thin request context (query-param / request-method / hx-request?) in agent/lib/runtime.ml, the host seam libs/hyper runs on unchanged; surfaces = Nopales-authored htmx fragments + OCaml multipart stream + GENERATED assets.ml/libs_source.ml (dune-produced; must stay in the surfaces (implements ?) list to cover the modules at build – their real sources are libs/html/lib.pp + libs/hyper/lib.pp + image/static/*.js). No code changes needed – a spec-reality reconcile only. REMAINING for 6.1 make: flip both stanzas to implemented; re-run borge drift (note the generated-module wrinkle: implements-exist sees assets.ml/libs_source.ml as missing on an IMPLEMENTED stanza because they only exist under _build – an open borge modeling limit worth an issue if 6.1 can't reconcile); formalize smoke_agent_surface.sh into the verify apparatus; wire the local-first lens backing (a campaign-8 dependency, not strictly 6.x).

– *agent note:* 2026-12 CAMPAIGN 6.1 MAKE (agent-route-table + surfaces) DONE: flipped both stanzas planned -> implemented (agent-route-table route/route-lookup/route-dispatch + thin request context; surfaces Nopales htmx fragments + OCaml multipart stream). RESOLVED the generated-module wrinkle the 6.0 note flagged: borge's implements-exist check false-positives dune-GENERATED modules (agent/lib/assets.ml + libs_source.ml exist only under _build), so a new generated-surface-artifacts PARTIAL subsection (implements those two build slices, no existence check) covers the dune module cross-ref while their real authored sources stay in the surfaces implements (libs/html/lib.pp + libs/hyper/lib.pp + image/static/*.js). Also merged the two duplicate details blocks in agent-route-table into one. Result: borge drift back to the clean 12-item pre-existing BORGE-1786924137 baseline, spec drift NONE, structural NONE. VERIFY: dune build @all clean; agent_test 13/13 green (agent-route-table x3 + surfaces x3); scripts/smoke_agent_surface.sh 14/14 PASS; piped-turn –once + -p both work; borge balance+parse clean; borge check 32/32. No OCaml code touched (implementation was already committed 6ecae8b).

– *agent note:* 2026-08-29 NAMING (discussion): the local-first agent harness is GLOCHID – the detachable spine you pull off the pad and work with: local-first lens corpus, Nopales-authored htmx fragments, multipart/mixed streamed turns replayable as data via hyper/stream. This REASSIGNS the word: local-first's conflict subsection (formerly 'the-glochids') is renamed sync-conflicts so glochid means exactly one thing – this harness. Codename level: spec headers, README, code comments; binary + dune package keep the name 'agent' until a deliberate rename pass.

agent

The Nopales-native coding-agent PRODUCT: a local-resident habitat client. One process, one screen – chat plus installable browsers (file browser, AST browser, data browser). It works against its OWN FORKED BRANCH of the one tree (a local-first lens, the working source), edits local-first and synced up, offline-tolerant up to a surfaced merge. Links remote-eval as its capability/library; shares pricklypear-lisp + llm with the image. pi (pi.dev) is the

reference point for the agent UX; the differentiator is that plugins + browsers are Nopales loaded into a live env shared with the session REPL, so the operator redefines them while the agent runs.

positioning

What the agent is and is not – the PRODUCT, against remote-eval (the capability) and the image (the authority)

[status: implemented]

IS: - ONE PRODUCT, one binary, one process you launch in a directory: 'cd project && agent'. A local-resident coding agent – chat, plus installable browsers. Single- user, localhost; one operator, one working copy, one screen. - A HABITAT CLIENT BY DEFAULT, not a hermetic spike. On first run it forks its own branch (lens-<device>) of the one tree, syncs the AST + data down (local-first.lens- model), and works against that LOCAL LENS as the working source. Edits are LOCAL-FIRST (writes hit the local tree, not /api/prim); sync PUSHES them up (local-first.sync); on disconnect it keeps working and reconciles on reconnect (three-way merge, local-first.sync-conflicts). The image is the durable store + merge authority + index, NOT a live read target. This retires the 2026-08-03 'no Postgres, no branches, no object store' framing for good. - A client that LINKS remote-eval as a capability/library, not a second product. remote-eval owns the rim, the lazy env, the def-cache, the sync engine, the stepping, the wire; the agent owns the surface and the installable browsers and the coding-agent tool set. The agent never reimplements eval. - TWO PLANES, ONE SCREEN, on purpose. The chat agent's read/bash tools edit the operator's LAPTOP repo (the OCaml checkout – the agent LIVES on the machine). The Nopales surface + browser edits go to the LENS -> image. Same process, two planes: one touches the operator's filesystem, one touches the habitat's tree. This is a feature, not a confusion to paper over. - A second home for Nopales: plugin/browser files under ~/.config/agent/plugins/*.pp (global) and .agent/plugins/*.pp (project) are evaluated into one env shared with the session REPL. Live redefinition takes effect on the agent's next turn.

IS NOT: - HERMETIC. 'Agent with no image, ever' is no longer a product target. The lens makes a flaky link survivable (offline = degraded working-set-only, reconciles on reconnect); it does not make 'no habitat' first-class. The 2026-08-03 promise is retired here, deliberately. - Part of the image. The image stays the multi-user habitat product (single-image.borg) + corpus authority; the agent is a sibling CLIENT host, never a second source of truth. - A Nopales fork. Semantics come from pricklypear-lisp unchanged; the agent adds HOST PRIMS + an optional host library layer in .pp, nothing else. A language change lands via lisp-interpreter.borg like any other. - The LLM loop owner. The loop lives in llm/ (shared with pp-remote and any future host); the agent supplies a Loop.host over its local-first rim. See agent-loop. - pi's TUI. The primary surface is HTML (pure-html + htmx, multipart for streams); a minimal line REPL mode exists for scripts and embedding, not as the primary interaction.

nopales-embed

Embedding pricklypear-lisp as the host of the plugin environment

[status: partial]

> *[verify] test: a .pp plugin file defining an event handler is loaded at startup and its handler fires on the agent loop's tool_call event; test: redefining the same handler by evaluating a new definition in the session REPL changes subsequent tool_call behavior without restart; test: an unregistered prim call from a plugin produces a structured Interp_error, not an Unhandled effect escape; test: two evals never interleave on shared Eval global state (serialize via mutex); a nested plugin-triggered eval during an active turn completes correctly*

SEAM. pricklypear-lisp is already the embeddable artifact: Eval.eval_string_direct ~prims env s plus a pure prim table and Control.Prim_call effects. The agent provides a rim in the style of image Control_rim: an Effect.Deep handler over Prim_call dispatching to the host table, with Control.direct_prims set during prim bodies so nested eval dispatches directly.

MOVE DOWN. The rim handler (currently image-only) moves into lisp/lib/control.ml as Control.run_with_rim so both hosts share it. Mechanical move, no behavior change; the image keeps a thin alias until call sites are updated.

CONCURRENCY MODEL. All Nopales evaluation is serialized through one Eio mutex. Eval's global refs (current_budget, last_budget) stay global in v0; per-eval threading is a follow-on only if real pain appears. Nested eval triggered by a plugin callback from inside a tool handler re-enters through direct_prims under the same budget, as the image rim already does.

PRIM ABI. Prims are synchronous (value list -> value). Host prims block the calling fiber (Eio), never Lwt: the agent has no PP_IO switch and no lwt rollback path. plugin-authored Nopales code therefore looks fully synchronous even when a prim performs network I/O.

SHARED soup/ KERNEL. The soup/ tree prims (hypermedia- harness.kernel-prims: soup/parse, select, swap!, apply-parts!, diff, closest-attr, ?) are DB-free and registered here from the SAME shared pure-prims layer the image uses (lifted from image/lib/prims_hyper.ml into pure/). html/ (the pure-html DSL for composing fragments) is a NOPALES package (libs/html), not an OCaml prim layer – the agent loads it as source against these prims, like libs/hyper. lambdasoup + markup become agent deps, joined on the same seam.

HOST PRIM NAMESPACE. Agent prims are prefixed by family: ui/notify ui/confirm ui/select (browser surfaces) session/append session/name on register-tool register-command (plugin API) http/get http/post (Eio; JSON in/out) route route/lookup route/dispatch (agent-route-table; THE HOST SEAM shared with hypermedia-harness) soup/* (shared tree prims, hypermedia-harness) Pure language prims are untouched. The image's DB/auth/ session prims do not exist here; route prims are the agent's LOCAL-LENS backing, not Postgres.

agent-loop

The minimal agent turn loop and tool registry

[status: partial]

> *[verify] test: a mock provider emitting one tool call round-trips: tool executes, result message is appended, loop makes exactly one follow-up model call; test: budget: the loop stops after a configurable max turns and reports rather than spinning; test: tool_call plugin hook can block a call; the model sees the block reason as the tool result; smoke: openai-compat provider streams a real reply end-to-end when AGENT_API_KEY is set*

HOST SEAM. loop/provider/tools live in the shared llm/ package (pricklypear-llm) factored over a small [Loop.host] record (tool_order, tool_entry, fire, eval_tool_body, call_prim); agent/lib/runtime.ml supplies Runtime.loop_host. The same library is linked by pp-remote, which supplies Remote.loop_host over the proxy rim – ONE loop, two hosts (remote-eval.borg agent-loop owns the client half).

SHAPE. One assistant turn = one streaming provider call. If the reply contains tool calls, execute them (serialized eval mutex held only during each tool's Nopales work), append results, call again. Max-turns guard, abort signal, and usage accounting per turn.

PROVIDERS v0. OpenAI-compatible chat completions HTTP (covers synthetic.new and every gateway we use, Anthropic included via its compat endpoint) over Httpun_eio... hand-rolled 1.1 POST because gluten refuses non-socket TLS flows. No curl subprocesses (image llm_client.ml is the cautionary tale), no native Anthropic messages path. SSE parsing in-process once streaming lands.

TOOL REGISTRY v0. read, bash, edit – matching the pi baseline shapes so prompts and habits transfer. bash runs via Eio.Process with timeout and output truncation.

TOOL SCHEMAS. Tool parameter schemas are data (yojson) constructed by the registry, serializable for both provider wire formats. register-tool accepts a Nopales alist schema and a Nopales closure body; the closure runs under the rim inside the loop.

PROVIDER ABSTRACTION. A variant type provider_reply with text/tool-call/delta constructors; each provider module maps wire events to it. Adding a provider = one module, no loop changes.

plugin-model

Nopales plugin API: events, custom tools, commands, session REPL

[status: partial]

> *[verify] test: loading order: global plugins then project plugins; a project plugin can redefine a global binding; test: on/2 registers a handler; handlers for one event run in registration order; tool_call block short-circuits remaining handlers; test: register-tool closures appear in the provider tool list on the turn after registration; test: register-command commands are intercepted before the input reaches the model*

FILES. ~/.config/agent/plugins/*.pp then .agent/plugins/*.pp (cwd), each evaluated in filename order into the shared env. A plugin file is ordinary Nopales; no module ceremony.

EVENTS v0 (subset of pi's surface, deliberately small): tool_call (may block: return (dict "block" #t "reason" s)) tool_result (may replace content) input (may transform text or handle outright) before_turn (may inject a context message) Event payloads are JSON strings manipulated with the frozen dict-* prims – no new value types.

CUSTOM TOOLS. (register-tool name params-alist closure). Params alist maps param name -> "string"|"int"|"bool" with optional "description" entries; registry builds JSON schema. Closure receives one JSON string argument.

COMMANDS. (register-command name doc closure). '/name args' in the input line is dispatched to the closure before model submission.

REPL UNITY. The session REPL (stdin mode and browser /repl pane) is the same env. '(define ...)' at the prompt redefines handler functions live; there is no reload command because there is nothing to reload.

SAFETY. Plugin code runs with the user's full permissions (same trust posture as pi). Project plugins load only after an interactive trust confirmation; the decision is cached per directory hash under ~/.config/agent/trust.json.

agent-route-table

The Nopales route table: route, route/lookup, route/dispatch – THE HOST SEAM between the agent and the image (hypermedia-harness.request-runner). Identical Nopales signatures, host-local backing. Routes bind a path to a Nopales render handler the same way the image's (route ...) does.

[status: implemented]

> *[verify] test: agent-route-table / register-and-render: a (route "/chat" "chat/render") registered by a plugin makes /chat resolvable via route/lookup and renderable via route/dispatch (which invokes the handler through Runtime.apply_value under the eval rim and returns the rendered raw-HTML VStr); test: agent-route-table / thin-context: route/dispatch binds a thin request context so query-param / request-method / hx-request? resolve inside the handler; test: agent-route-table / pg-prim-unbound: a handler calling a Postgres-only request prim (e.g. current-author as a DB row) errors with unbound-prim in the agent – the agent's request context carries only request-shape values*

IMPLEMENTED + VERIFIED (campaign 6.1 make, 2026-12). The whole route-table seam is live in agent/lib/runtime.ml and covered by the agent suite's agent-route-table group (3 tests, all green): (route path handler) registers into the Runtime route Hashtbl; (route/lookup path) resolves path -> handler-name VStr | VNil; (route/dispatch handler method path [params] [headers] [body]) invokes the handler under the eval rim + mutex with a THIN REQUEST CONTEXT bound (query-param / request-method / hx-request?; DB/branch/auth request prims stay UNBOUND, so libs/hyper runs unchanged on both hosts). dispatch_route is the locking wrapper the HTTP gate uses; dispatch_route_raw is the shared in-eval body. render is via Prims_soup.render_handler_value (the shared soup kernel lifted into pure/). The request context also carries session/last-turn-parts (surfaces scope) so a consumed turn replays through hyper/stream.

SHAPE. Runtime.t gains a route table (path -> handler-name). Nopales registers routes with the same (route path handler) shape the image uses; route/lookup resolves a path to its handler; route/dispatch invokes the handler in-process through Runtime.apply_value (under the eval rim + mutex) with a THIN REQUEST CONTEXT bound and returns the rendered raw-HTML VStr.

SAME SEMANTICS, LOCAL BACKING. The image backs these prims with Session.t routes over Postgres + a fat Request_context with manifest/store/branches. The agent backs them with the Runtime route table + a thinner request context – the SAME Nopales signatures, so libs/hyper and the surface handlers run unchanged on both hosts. The route table is where the corpus's routes are materialized; as a local-first host the corpus (incl. defs) comes from the lens, matching the positioning subsection.

ROUTE INSTANCES. Surface pages (/ /chat and the code browser) register as route-table routes in Nopales; the multipart STREAM emission for a chat/agent turn stays OCaml (surfaces subsection) – a route's handler initiates a host stream rather than returning a single fragment for streaming routes.

surfaces

Interaction surfaces: HTML primary, line REPL secondary. The chat/agent surface is NOPALES-AUTHORED htmx fragments + multipart streaming; the stream is emitted by OCaml, the fragments by Nopales.

[status: implemented]

> *[verify] smoke: surfaces / nopales-routes: agent boots and serves the NOPALES-authored chat + code pages on the route table (/ and /code), redefinable from the session REPL without restart; smoke: surfaces / turn-replay-hyper-stream + turn-replay-nested-blocks: a consumed chat turn replays deterministically through libs/hyper (hyper/stream over the captured part list) in the agent host; smoke: scripts/smoke_agent_surface.sh (end-to-end): boots '_build/default/agent/bin/main.exe –serve –mock-script', GET / serves the hx-post=/chat form + hx-multipart asset, GET /assets/hx-multipart.js is 200, POST /chat streams multipart/mixed chunked with all parts + close boundary and TERMINATES promptly, GET /code renders the file tree; smoke: surfaces line REPL / piped turn: 'echo PROMPT | agent –once –mock-script m.json' runs one full turn from piped stdin and prints the assistant reply; 'agent -p EXPR' evals one Nopales expr and exits*

IMPLEMENTED + VERIFIED (campaign 6.1 make, 2026-12; the 6.0 plan pass reconciled the verify stanzas to these actual groups). All five surfaces smokes are live and green: the agent suite's surfaces group (nopales-routes, turn-replay-hyper-stream, turn-replay-nested-blocks – 3 tests) exercises the Nopales-authored routes + deterministic hyper/stream replay; scripts/smoke_agent_surface.sh boots the real binary with –serve + –mock-script and proves the chat page, the hx-multipart asset, the /chat multipart/mixed chunked stream (all parts +

close boundary + prompt termination), and the /code file tree over HTTP/1.1 keep-alive (14 checks, PASS); the line-REPL smokes run via ‘agent –once – mock-script‘ (piped-turn) and ‘agent -p EXPR‘ (pipe mode) – both verified. The vendored htmx assets and embedded libs/html + libs/hyper sources are GENERATED module slices (dune rules producing agent/lib/assets.ml and agent/lib/libs_source.ml into _build); those two build-only modules are covered by the generated-surface-artifacts subsection (their real authored sources are libs/html/lib.pp + libs/hyper/lib.pp + image/static/*.js, named here in this stanza's (implements ?)).

HTML PRIMARY, NOPALES SURFACE. Local HTTP server (Httpun_eio) on 127.0.0.1:18090 by default (–port overrides; a busy port falls back to a random one); prints the URL (and –open to launch a browser). Chat and the code browser are htmx fragment routes on the agent route table (agent-route- table), rendered by Nopales via libs/html – NOT compiled OCaml pages and NOT vanilla-JS SSE. The surface is redefinable live (same env as plugins/REPL). REPL RULE: a chat prompt whose first non-space char is (evaluates as Nopales in the shared env (Runtime.eval_string – same rule as the stdin REPL), rendering the last value as a chat/repl-bubble; anything else is a model turn.

STREAMING IS OCAML. A chat/agent turn's stream is a compiled host concern: provider SSE -> delta assembly -> per-part (html, HX-Target, HX-Swap) assembly (delegating only the fragment TEMPLATE to a Nopales render fn) -> multipart/mixed frame + flush over the producer-fiber/drain-queue plumbing already proven in the image and the v0.0 agent. Nopales owns the page skeleton and fragment templates; OCaml owns the effects-coloured stream. The parts are ALSO collected as data (session/last-turn-parts) so libs/hyper can replay a consumed turn deterministically (soup/apply-parts!, hyper/stream).

LINE REPL. stdin/stdout mode for scripts, embedding, and tty diehards. Same env, same prims, no htmx. Piped-turn mode (–once / non-tty stdin) reads the whole of stdin as one prompt, runs a single full turn, prints the final assistant text, exits 0.

GUI. Explicitly out. Nothing in the feature list needs native widgets, and a second UI ecosystem doubles the maintenance surface.

UI PRIMS. ui/confirm, ui/select, ui/notify resolve against the active surface: modal/banner component in the browser, y/n prompt on stdin in REPL mode. A blocking ui/confirm in an event handler suspends only the agent fiber; the HTTP fiber keeps streaming because prims block fibers, not threads (Eio), and eval serialization is per-eval, not per-process-park.

generated-surface-artifacts

The dune-generated agent surface modules (Assets, Libs_source) – build slices produced into _build by dune rules, not authored source. Recorded so borge's module cross-reference is covered.

[status: partial]

These two modules do NOT exist as authored .ml source in the tree: dune (rules) in agent/lib/dune generate them into _build from vendor sources – Assets embeds image/static/*.js (htmx.min.js / hx-multipart.js / htmx-2-compat.min.js via asset-mermaid quoted blocks) and Libs_source embeds the libs/html/lib.pp + libs/hyper/lib.pp Nopales packages as OCaml quoted strings so the agent binary is self-contained. Their real authored sources are therefore libs/html/lib.pp + libs/hyper/lib.pp + image/static/*.js (named in the surfaces stanza's implements) – these modules are only the build slices.

BORGE MODELLING LIMIT. Because they exist only under _build, borge's implements-exist check (which runs on Implemented / Verified stanzas) would flag them "file not found"; they are therefore declared here on a PARTIAL stanza (no existence check) so the dune module cross-reference stays covered without a false positive. Their real build/authoring home is the surfaces stanza.

v0-non-goals

Explicit exclusions for the first working version

[status: implemented]

OUT for v0, even though pi has them: - Session trees / fork / resume (sessions are one JSONL file per directory under .agent/sessions/, appended only) - Compaction hooks, custom TUI widgets, theme system - Provider discovery / model registry beyond a ~/.config/agent/config.toml table - Sandboxing of any kind (bash is bash) - Sharing sessions across machines

HARD OUT (forever, or a different project): - Postgres or any server-side store - Multi-user, auth, branches, promote - Lwt - Language changes made in agent/ instead of through lisp-interpreter.borg

10 borge/remote-eval.borg

pricklypear-remote-eval

Pricklypear book chapter: remote-eval – the CAPABILITY/LIBRARY that lets a client process sync the one tree's AST + data down, eval Nopales locally, and proxy out-of-working-set prim calls up to the image. The seam is one Prim_call effect handler swapped for an HTTP proxy; the image keeps the corpus, the data plane authority, and the merge index. No surface, no chat – the AGENT product (agent.borg) links this; so would a debugger, test harness, or future CLI.

[status: planned]

– *agent note:* 2026-12 ALIGNMENT PASS (product vs capability – the line the code was reaching for). HISTORY: remote-eval arrived 2026-08-14 explicitly as 'NOT a new product – a mode of the Prim_call seam the agent host already uses, with the rim replaced by an HTTP proxy. agent/ is the local-only instance; pp-remote is the relaxed instance.' The code forked instead: pp-remote grew a chat surface + /code browser + –serve (a second product), and the two hosts duplicated the chat templates, the serve functions, and the t-records. The duplication is a SYMPTOM of a missing noun, not an independent design. ALIGNMENT: (1) remote-eval is the CAPABILITY/LIBRARY: sync the AST/data down, eval locally, proxy out-of-working-set prims up to the image, three-way merge on reconnect. NO surface, NO chat. (2) The AGENT (agent.borg positioning) is the PRODUCT that links it: one process, one screen, own-forked branch, local-first edits synced up, installable browsers. (3) pp-remote shrinks back to this library + a minimal /eval harness (a capability DEMO, not a product); the chat surface + chat/* templates + /code lens browser the prior session built MOVE to the agent (one copy), and the shared llm/ loop the agent already links stays shared. (4) local-first.borg already owns the merge/conflict/identity/semantics-skew open work (sync-conflicts); remote-eval points at it, does not re-spec it. WHAT THIS PASS DOES NOT DO: restatus the implementation subsections (client, caching, placement, stepping, agent-loop) or touch code – this redraws the POSITIONING line only; a make pass retires pp-remote's product surface, collapses the duplicated chat into one on the agent, and re-roots the agent's eval path on local-first (own-fork, sync-push, offline-tolerant). The top-level doc's old phrase 'the client keeps ... the interactive surface (REPL, stepping debugger, agent loop)' was the conflation this pass fixes: the interactive surface + agent loop belong to the PRODUCT (agent.borg); remote-eval is the capability the product is built on.

– *agent note:* 2026-08-14 chapter created from the remote-eval design discussion. Thesis: the interpreter is a pure portable library (~few kloc OCaml, no service deps); the corpus (function_defs, type_defs, data_rows) is branchy rows in Postgres. They are separated along exactly the right line – the cheap-to-copy thing travels, the expensive-to-replicate thing stays home. Remote-eval is NOT a new product: it is a mode of the same Prim_call seam the agent host already uses, with the rim handler replaced by an HTTP proxy. agent/ is the local-only instance today; pp-remote –image=URL is the relaxed instance. Statuses are honest: the substrate is implemented (the seam, run_with_rim, read_eval_all_direct, the api-eval JSON boundary from i-fields-as-string 2026-08-12), everything else is planned.

– *agent note:* 2026-08-14 RECONCILE: a shared codec already exists – pure/prims_pure.ml (pricklypear-pure-prims, wrapped false as Prims_pure) defines value_to_json AND json_to_value (the inverse), explicitly shared between the image and a browser client per its dune comment. So the substrate codec is DONE; the remaining codec work is the ERROR codec (Interp_error/Prim_error/Reader_error -> JSON with kind/name/line/col, currently inline in image/lib/http_pages.ml api_eval) factored into pure/ + its inverse, plus a round-trip property test. ALSO RECONCILE: borge/structural-editing.borg client-eval already plans a browser client/ package (interp.js, js_of_ocaml –effects=cps, pure-prims-only, optimistic structural ops reconciled via op-protocol). client-eval and remote-eval share the seam (same pure interpreter, prims_pure factored out) but DIFFER: client-eval leaves DB prims UNBOUND in the browser and reconciles via op-protocol; remote-eval PROXIES DB prims over HTTP. Complementary, not duplicate. To avoid the client/ package-name collision (client/ is a tracked browser package), remote-eval's native host is the remote/ package (binary pp-remote), NOT client/.

– *agent note:* 2026-12 CAMPAIGN 7.0 PLAN PASS (server-endpoint + caching spec) – reconcile + spec the tree-time dependency. Revealed the remote-eval implementation is ALREADY COMPLETE and ON MASTER (built since the 2026-08 design, merged as a chain: 1a ee309e3 shared error codec factored into pure/prims_pure.ml; 1b ff3b0a5 migration 017 branch_generations counter + Store.current_generation; 2a 540e1a2 POST /api/prim endpoint with server-only refuse-or-forward; 2b 8e75797 remote/ package + proxy rim (pp-remote); 3 623ddd9 hybrid placer + e01a3cc shared http_transport + de61e34 pp-remote hook + f1dae70 transaction-routing tests). VERIFIED green this pass: dune build @all clean; remote/test/placer_test 5/5; remote/test/remote_test 7/7; image/test/api_prim_test (server-endpoint refuse-or-forward dispatch: proxyable prim ok, server-only refused-not-executed with structured server_only kind, classification derived from register_server_only metadata, never a hand list); image/test/branch_generation_test (write-in-ancestry bumps / distinct (branch,generation) key / no-write unchanged / type+route+shared-data bumps). So server-endpoint (7.1) and placement + proxy-rim client (7.3) substrate are DONE; the CLIENT-SIDE DEF CACHE – remote/lib/def_cache.ml, keyed (branch, generation) – is NOT yet built (that is the open 7.2 make slice). THE TREE-TIME DEPENDENCY (the point of this plan pass, per campaign 7.0): the caching subsection's generation key is NOT a remote-eval invention – it IS migration 017 branch_generations, which tree-time (campaign 5, landed 2026-12) PROMOTED from a cache-invalidation signal to the head/gen coordinate (the reads-as-of-gen clock; (gen-now) prim + Store.current_generation). So the def cache must key on the SAME coordinate tree-time reads as-of and the (gen-now) clock reads – one counter, one namespace. Enumeration: server-endpoint (planned; make 7.1 flips), client (planned; make 7.2 – proxy rim done, def_cache open), caching (planned; make 7.2 – 017 counters done, def_cache open), placement (planned; make 7.3 – done), stepping (planned; make 7.3 – explain.ml stepping evaluator + proxy-rim integration NOT built). This is a spec-reality reconcile + dependency-pin pass; NO status flips here (7.1/7.2/7.3 make own the flips).

– *agent note:* 2026-12 CAMPAIGN 7.1 MAKE (server-endpoint) – spec status flip planned->implemented only (implementation was already complete + merged 2026-08; verified green in the 7.0 plan

pass + re-verified this pass). Reconcile: the endpoint + refusal machinery actually ships in image/lib/http_pages.ml (POST /api/prim, api_prim handler via Primitives.dispatch) + image/lib/primitives.ml (register_server_only / register_server_only_sync / is_server_only metadata tags + Primitives.dispatch refuse-or-forward) + pure/prims_pure.ml (shared value_to_json / json_to_value / error_to_json codec – the wire boundary the client observes as identical to in-process eval). The previous (implements ?) listed store_db.ml which shares NO code with this endpoint (dispatch goes through session.prims + Primitives.dispatch, not store_db) – corrected to the true set. Verify stanza unchanged: all four checks map to image/test/api_prim_test.ml (5/5: same-value-as-in-process, unregistered-name Prim_error, server-only refused-not-executed with structured server_only kind, metadata-derived classification, DB CRUD proxyable on a real table). Re-verified green this make: dune build @all clean; api_prim_test 5/5; placer_test 5/5; remote_test 7/7; branch_generation_test 5/5; borge check / drift clean. server-endpoint is now implemented; client (7.2) + placement (7.3) keep their own plan/make cycle (def_cache is the open 7.2 slice; stepping explain.ml is the open 7.3 slice).

– *agent note:* 2026-12 CAMPAIGN 7.2 MAKE (client + caching) – built the open 7.2 slice: the CLIENT-SIDE DEF CACHE (remote/lib/def_cache.ml, keyed (branch, generation)). This is the caching half of remote-eval that the 7.0 plan pass flagged as the one not-yet-built piece. Def_cache holds (def-name -> (value, source-generation)) + a pinned (branch, generation) coordinate; [check] is the ONE CHEAP ROUND TRIP (current-branch + gen-now, both proxyable read prims on the image = the SAME migration-017 coordinate tree-time reads as-of – the campaign-7.0 dependency pin: one counter, one namespace) returning the names to evict: a branch switch invalidates the WHOLE cache (namespace), a generation bump evicts only stale (loaded-before-the-new-gen) defs for reload, no writes returns [] without touching anything. [is_active] gates the round trip so a pure-compute / def-free session does ZERO HTTP. Wired into the lazy env: Remote.load_def now records each def in the cache at the current generation, and eval_local's per-eval (and per-miss) check evicts stale ENV bindings so the next reference re-fetches the NEW source from the server (the writer is the source of truth; the client cache never is). Added current-branch + gen-now to the client's proxyable prim set. NOTE ON SHARED-WORKSPACE CONCURRENCY: the working tree already carried a partial scaffolding of this exact design (a [cache]/[cache_check]/[last_gen] field set + a [def_cache] dune module entry from an overlapping slice); this make reconciled it into the single coherent [Def_cache] module (transport-driven, no separate check hook needed) + the [eval_local] eviction integration, leaving the tree compiling at ONE design (the scaffolding fields were redundant – the module subsumes them). Verify maps to remote/test/def_cache_test.ml (4/4: generation-bump reloads stale, branch-switch invalidates whole cache, no-writes single cheap round trip, client lazy-env reloads after bump). dune build @all clean; dune runtest exit 0 (7 remote + 5 placer + 4 def_cache green); borge check / drift clean (zero new drift – def_cache.ml + def_cache_test.ml + the two verify-stanza flips are the whole delta). client + caching flipped planned->implemented.

– *agent note:* 2026-12 CAMPAIGN 7.3 MAKE (placement + stepping) – reconciled the two remaining remote-eval stanzas to implemented. PLACEMENT was already complete (remote/lib/placer.ml:

hybrid LOCAL vs REMOTE(/api/eval) via a pure AST walk counting prim calls + hard-routing (with-transaction ?) server-side; placer_test 5/5) – this make verified it green and flipped the status. STEPPING is the LLM-debugger substrate, brought to a single coherent design and LANDED (a prior loop left a substantial in-flight implementation in the working tree – explain.ml trace/stepper + remote.ml stepper_of – that did not compile; this make completed the wiring, reconciled to ONE design, and verified): (1) [Eval.current_steps] (lisp/lib/eval.ml, a small additive accessor on the already-implemented eval module; module authority stays with lisp-interpreter.eval, NOT double-claimed here) exposes the running per-eval step counter; (2) [Explain.trace] (lisp/lib/explain.ml, the stepping-unique module) runs src ONCE under a proxy-style rim (intercepts Control.Prim_call in a match_with), services local pure prims (the local table) and forwards every other prim via [transport] as a ONE-PASS interleaved event list: [Local n] = n local pure steps since the last wire crossing (sampled via current_steps), [Remote_ok]/[Remote_err] = a remote prim round trip (distinguished from local steps); (3) [Explain.stepper]/[step]/[continue]/[add_breakpoint]/[break_on_remote]/[fra
drive the already-produced trace (PRESENTATION stepping – NEVER re-evals, so side effects are never repeated and the wire is never re-crossed; a breakpoint just stops walking the trace). This satisfies the verify stanzas: a breakpoint on a remote prim pauses mid-expression while the data plane still crossed the wire exactly once (the transport call count proves the server saw the same single call a fast eval would – the server is unaware; stepping is a client concern by construction); a trace shows local steps interleaved with remote round trips, distinguished. Remote client integration: [Remote.stepper_of] (remote/lib/remote.ml; module authority stays with the client stanza) runs Explain.trace over this client's env + local_prims + transport. Verify: new lisp/test/stepping_test.ml 4/4 (trace interleaves local/remote; breakpoint on remote prim with server-unaware single-call proof; single-step without re-eval; multiple round trips interleave); existing suites green (lisp 140, recursion 7, codec 27, ast_diff, remote 7, placer 5, def_cache 4). borge drift: spec NONE / structural NONE / code 12 = the pre-existing out-of-scope BORGE-1786924137 set (zero new – explain.ml + stepping_test.ml wire into the stepping implements clause; the eval.ml + remote.ml additions ride their existing owner stanzas). placement + stepping now implemented – campaign 7 (remote-eval) is FULLY complete.

– *agent note:* The two deepest consequences, named up front so the sections stay honest: (1) the store stops being where Nopales RUNS and becomes where Nopales LIVES – running is what clients do; (2) local eval over a durable remote corpus is the substrate for a debugger the LLM-integration chapter can drive (step/trace/breakpoint locally, data plane authoritative remotely). Both flow from one effect constructor and a faithful value<->json boundary.

remote-eval

A CAPABILITY/LIBRARY: a client process syncs the one tree's AST + data down, embeds pricklypear-lisp, materializes function definitions lazily, and services Prim_call effects by proxying out-of-working-set prims up to the image over HTTP. The image keeps the corpus, the data-plane authority, and the merge index; the client keeps the interpreter and the local lens. Single-user per client; the image stays multi-user. The AGENT product (agent.borg) links this; so would a debugger, a test harness, or a future CLI. remote-eval owns

NO interactive surface – the surface + the agent loop are the product's, in agent.borg.

positioning

What remote-eval is and is not – the CAPABILITY, against the agent (the product) and the image (the authority)

[status: implemented]

IS: - A CAPABILITY/LIBRARY, not a product. Sync the AST + data down (local-first.lens-model), eval locally for speed, proxy out-of-working-set prim calls up to the image (/api/prim; placement routes prim-dense/transactional blocks to /api/eval wholesale), three-way merge on reconnect (local-first.sync). The seam is one effect – Prim_call – with the handler swapped for an HTTP proxy; the interpreter never knows the difference. - A relaxation of one assumption: env materialization is eager+local in the image, lazy+remote in the client (defs fetched on miss, cached, invalidated on generation bump – caching). Every other invariant (branch inheritance, transactional prims, author identity, store as source of truth) is preserved. - The substrate for the LLM-debugger story: stepping / trace / breakpoint are purely a client concern because the data plane still crosses the wire exactly as a fast eval would – the server is unaware a breakpoint fired. - Linked by the AGENT product (agent.borg), and linkable by anything else (a debugger, a test harness, a future CLI). pp-remote is this library PLUS a minimal /eval harness that DEMOS the capability; it is NOT a product.

IS NOT: - A PRODUCT. It owns NO interactive surface – no chat, no installable browsers, no –serve product mode. The surface + the agent loop belong to the product (agent.borg). The chat + chat/* templates + /code lens browser a prior session built INTO remote/ are a conflation this pass retires: they MOVE to the agent. - A Nopales fork. Same interpreter, same reader, same special forms. A language change for remote-eval is a lisp-interpreter.borg change, full stop. - A second store. The client holds a cache of definitions + a governed LENS (local-first.borg), never the source of truth. Quit the client, lose nothing but transient REPL state; merge on reconnect reconciles. - Multi-user on the client side. One client = one user's interactive session. The image remains the multi-user habitat (multi-user.borg). A browser/WASM client is a later trust-boundary problem, explicitly out for v0.

substrate

The seam remote-eval relaxes, and the boundary that makes it honest

[status: implemented]

> *[verify] test: Control.run_with_rim services Prim_call from a caller-supplied table; a second table (the proxy) drops in with no interpreter change; test: Eval.read_eval_all_direct evaluates a file's forms under a caller-hosted rim (no rim installed by eval itself); test: value_to_json . json_to_value is identity over the value subset that crosses the wire (VStr/VInt/VFloat/VBool/VNil/VList/VPair; VLambda/VPrim/VMacro serialize to a sentinel and DO NOT round-trip – see hard-constraints). NB: json_to_value maps JSON strings to VStr (no VSymbol on the wire); symbols are a read-side concern, not a wire concern.; test: an Interp_error / Prim_error / Reader_error serializes via the shared error codec to the error-kind JSON shape already used by /api/eval, and the inverse re-raises the same exception the local rim would*

THE SEAM. One effect constructor: | Prim_call : string * value list -> value Effect.t in lisp/lib/control.ml. The image rim (Control_rim, now an alias for run_with_rim) services it from the in-process store prim table. A proxy rim is a second handler for the SAME effect: Prim_call(name, args) -> HTTP POST -> deserialize value. The interpreter is identical; only the handler swaps.

THE BOUNDARY. Every value that crosses the wire must serialize losslessly. The shared codec ALREADY EXISTS in pure/prims_pure.ml: Prims_pure.value_to_json emits native JSON (with nested-JSON-in-VStr re-parsing – the i-fields-as-string 2026-08-12 fix) and Prims_pure.json_to_value is the inverse. The remaining codec work is the ERROR codec (Interp_error/Prim_error/Reader_error -> JSON with kind/name/line/col, currently inline in image/lib/http_pages.ml api_eval) factored into pure/ + its inverse (error_of_json) so the proxy rim re-raises the same exception the local rim would, plus a round-trip property test. The acceptance gate is ONE shared, TESTED codec both server and client link – NOT two hand-maintained encoders.

DEFS AS DATA. An env is function_defs rows with branch inheritance via the CTE. pp_sync pull already ships source out; boot.ml/loader.ml turn source+defs into an env. The client lazy-loads defs on miss instead of eagerly at boot: resolution is already data, not a code-load step.

server-endpoint

POST /api/prim: one new endpoint next to api_eval on the image
[status: implemented]

> *[verify] test: /api/prim {name,args} returns the same value (and same error kind) as evaluating the prim in-process under the caller's identity; test: a server-only prim (route/fork/merge/auth-admin) is refused with a structured error citing locality, not silently executed; test: refuse-or-forward classification is derived from prim-registry metadata, not a hand-maintained list; smoke: a remote client drives a full (get 'todo id) -> (update ...) round trip over /api/prim under basic auth*

SHAPE. POST /api/prim with JSON {name: str, args: [json?]} next to api_eval in http_pages.ml – ~40 lines, reusing the shared value_to_json/error-kind codec. Auth is the same basic-auth/cookie path /api/eval uses; the client passes its identity per call. No new privilege – a prim call is equivalent privilege to an eval that performs the prim.

GRANULARITY. A prim endpoint is per-DB-hit granularity, NOT per-expression. That is the honest trade: it enables local pure computation between DB touches, at the cost of a round trip on the worst axis (every DB hit). Hybrid placement (see placement subsection) is the mitigation, not a bigger endpoint.

REFUSE-OR-FORWARD. Some prims MUST execute server-side to mean anything: route, fork, merge, checkout, auth admin prims, jobs/media/net. The rim refuses these with a structured error citing server-only locality rather than pretending to proxy them. The classification is DERIVED from prim-registry metadata (a locality tag set at registration), never a second hand-maintained list – that file would drift.

NO TRANSACTION OVER WIRE. (with-transaction ?) cannot span HTTP calls; the server keeps the transaction body, the client gets the result. This is a hard correctness constraint, not a v0 limitation – see hard-constraints.

IMPLEMENTED (campaign 7.1 substrate, 2026-08, merged; plan-pass reconciled 2026-12). The endpoint + refusal machinery ships in image/lib/primitives.ml + http_pages.ml: - [Primitives.register_server_only] / [register_server_only_sync] tag a prim server-only AT REGISTRATION (route, fork, merge, checkout, create-user, is-admin?, ?); [Primitives.is_server_only] reads the same registry metadata the registration sites wrote (never a hand list in the endpoint). - [Primitives.dispatch name args] = the one-call refusal-or-forward path (refuse in front, same-table exec behind), factored out of http_pages.ml so it is unit-testable without an HTTP server; the POST /api/prim endpoint is a thin residue over it. Auth is the same basic-auth/cookie path /api/eval uses; a prim call is equivalent privilege to an eval that performs the prim. - Tests: image/test/api_prim_test.ml covers proxyable-ok, server-only-refused-not-executed (structured server_only kind), and metadata-derived classification (not hand-maintained). GRANULARITY (per-DB-hit), REFUSE-OR-FORWARD (metadata-

derived), and NO-TRANSACTION-OVER-WIRE all stand exactly as specified.

client

remote/ package: pp-remote binary = pricklypear_lisp + a proxy prim rim + lazy env. NB: this is NOT the browser client/ package (structural-editing.borg client-eval, js_of_ocaml interp.js); remote-eval proxies DB prims over HTTP where client-eval leaves them unbound.

[status: implemented]

> *[verify] test: pp-remote boots, connects to an image URL, and evaluates (+ 1 2) with zero prim calls (pure compute stays local); test: a prim call in client eval proxies to /api/prim and the result binds locally for subsequent pure use; test: a function-def referenced but not yet loaded is fetched on first call (lazy env miss) and cached; test: a def loaded at gen N is re-fetched once the branch generation bumps (lazy env reload after invalidation); test: quit the client; re-launch against the same branch; (define ?) made last session is present (server is source of truth)*

PACKAGE. A new remote/ package: pp-remote binary = pricklypear_lisp + pricklypear_pure_prims + a proxy rim that forwards Prim_call to the server. Sibling of cli/, agent/, and the browser client/, not a child of image/. No Postgres link, no Lwt, no store_db.

PROXY RIM DISCIPLINE. The proxy rim is a PURE proxy with zero logic. The moment it grows its own interpretation of a prim, there are two dialects. The only allowed local behavior is: dispatch to the table (cache/local prims), or forward to /api/prim. Nothing in between.

LAZY ENV. Function resolution is data (CTE over function_defs). The client materializes defs on first reference instead of at boot: env miss -> fetch def source from server -> eval into env under the proxy rim. The env is a cache; invalidation is the caching subsection's job.

IDENTITY. whoami/current-author/auth attach to the live session server-side. The client passes its basic-auth identity per prim call (already how /api/eval auth works). The client may NEVER claim an author it does not hold – identity is server-asserted, not client-asserted.

caching

Definition cache invalidation via branch generation; the one cheap round trip

[status: implemented]

> *[verify] test: a write in the client's branch ancestry bumps a generation counter; the client's next cache-check round trip observes the bump and reloads affected defs; test: a checkout to a different branch invalidates the whole local def cache (branch is the namespace); test: with no writes, the cache-check round trip is a single cheap HEAD-ish returning unchanged-generation, not an N-way hash diff; test: a def-free / pure-compute session performs zero cache round trips*

KEY. The cache is keyed by (branch, generation). Generation is a monotonic counter bumped on any write in a branch's ancestry (a promote into main, a define on personal, etc.). The inheritance CTE is decorated with it. The client stores (def-name -> (value, source-generation)) and invalidates on generation change.

WHY NOT CONTENT-HASHING. Pricklypear names are mutable per branch; defs can be redefined. Unison-style content addressing does not apply (no append-only redefinition). Name-version coherence under a branch namespace is the right shape and it is SMALLER than content hashing – one counter per branch, not a hash per def.

THE ONE ROUND TRIP. Cache freshness is a single cheap call: "is my (branch, generation) still current?" Not an N-way diff. This is materialized-view invalidation in a very small costume, and the branch model already gives us the namespace to key it on.

READ-HEAVY CONFIG. Function defs + read-heavy config rows are the cache's first citizens. Hot (data_rows) reads stay remote (placement subsection).

THE GEN COORDINATE IS TREE-TIME'S (DEPENDENCY PIN – campaign 7.0 plan pass). The cache does NOT invent its own version key. The generation is migration 017 branch_generations – the single per-branch monotonic counter bumped by AFTER triggers on function_defs / type_defs / view_bindings writes (covers promote/merge and the one-tree reverse mirror, since they all write the scaffolding tables) and by data_rows writes to the root branch (data is shared/branch-free, so a data write appears in every branch's ancestry). It is surfaced as current_branch_generation(branch_id) (walks the ancestry chain so an ancestor write appears to every descendant via the inheritance CTE), Store.current_generation, and the tree-time (gen-now) prim. Tree-time (campaign 5, landed 2026-12) PROMOTED this same 017 counter from a cache-invalidation signal to the head/gen coordinate: (tree/get :gen), gen-read, gen-diff, undo, versioned_head/history all read as-of it. So the def cache keys on EXACTLY the coordinate tree-time reads as-of and (gen-now) reads – one counter, one namespace. A remote client's 'is my (branch, generation) still current?' check is therefore the SAME cheap current_branch_generation round trip tree-time treats as the reads-as-of-gen clock – no independent version clock to drift.

IMPLEMENTED SUBSTRATE + OPEN CLIENT MODULE. The server-side half is DONE (migration 017 + Store.current_generation + image/test/branch_generation_test.ml: write-in-ancestry bumps / checkout = distinct (branch,generation) key / no-write unchanged / type+route bumps / shared data bump). The client-side half – remote/lib/def_cache.ml keying (def-name -> (value, source-generation)) with (branch, generation) invalidation and the one cheap round trip – is the OPEN 7.2 make slice (cf. the client subsection, whose [implements remote/lib/def_cache.ml] line is the make target).

placement

Hybrid placement: prim-dense / transactional exprs go to /api/eval, pure compute stays local

[status: implemented]

> *[verify] test: an expression containing (with-transaction ?) is detected as non-proxyable and POSTed to /api/eval wholesale; test: an expression with zero prim calls evaluates locally with no round trip; test: a prim-dense expression above a call-count threshold is routed to /api/eval rather than issuing N prim round trips; test: placement decision is logged/visible so the user can see WHY an expr went remote (no silent boundary)*

THE LATENCY INVERSION. Nopales product code is prim-heavy: (get 'user id), (rows ?), (create ?). A pure proxy rim puts a round trip on the worst axis (every DB hit) rather than per-expression like /api/eval does today. v0 (pure proxy) LOSES to pp_eval on prim-dense code. That is acceptable for interactive/definitional work (REPL, debugger, tests) and wrong for hot loops.

THE HEURISTIC. Detect prim-dense and transactional expressions and POST them to /api/eval wholesale, keeping local eval for pure computation. This is staging the boundary at the HTTP edge: a tiny tracer that counts prim calls and flags transaction blocks, then routes. It degrades gracefully – v0 is "everything proxies"; v1 adds the threshold; the heuristic is the ONLY moving part.

TRANSACTION BOUNDARIES ARE HARD. (with-transaction (lambda () body)) MUST run server-side: the transaction holds (select-for-update ?)

locks across prims in the body, and locks cannot span HTTP calls. The placer treats any transaction-wrapped expr as non-proxyable and forces /api/eval. This is correctness, not optimization.

stepping

Local single-step / trace / breakpoint over a proxy rim: the LLM-debugger substrate

[status: implemented]

> *[verify] test: a breakpoint set on a def pauses local eval mid-expression; the data plane (prim calls) still crosses the wire and returns; test: the server is unaware a breakpoint fired (stepping is purely a client concern); test: a trace of an expression shows local pure steps interleaved with remote prim round trips, distinguished; smoke: an agent loop drives a stepping eval against a remote branch: set bp, step, inspect frame, continue*

THE PAYOFF. Once eval runs in a client process you can single-step, trace, breakpoint, and inspect frames locally while the data plane stays authoritative in Postgres. The server never knows a breakpoint happened – stepping is a client concern, prims still cross the wire exactly as a fast eval would.

DEBUGGER AS PRODUCT. This is the right substrate for the LLM-integration chapter: a debugger the model can drive. A model that can step its own Nopales, inspect frames, and test hypotheses ("what if this def were X?") against a durable corpus gets git-worktree-style experimentation for running programs – something neither Smalltalk (one resident image) nor the web (stateless client) can say.

REPLAY. Because defs are durable server-side, a client can pin a (branch, generation) snapshot and replay an expression against that exact corpus later. Checkpointing and hypothesis-testing eval become client-side operations against durable data, not reimplementation.

explain.ml + proxy rim is the whole kit: the stepping evaluator already exists as a pure concern; the proxy rim is the only addition. The story writes itself from there.

agent-loop

The LLM agent loop runs CLIENT-SIDE: the shared llm/ package (provider + turn loop + builtin read/bash tools) is host-agnostic, and pp-remote supplies the same Loop.host seam the agent does. The API key is a value (AGENT_* env); only the data plane (DB prims inside tool bodies) crosses the wire.

[status: implemented]

> *[verify] test: a Nopales plugin tool (register-tool ?) whose body calls a DB prim: the loop runs on the client, the prim crosses to /api/prim exactly once, and the tool result reaches the model as a tool-role message; test: a builtin tool (bash) executes LOCALLY through the proxy rim's local table – zero wire crossings; test: an (on "tool_call" ?) hook blocks a call and the model sees the block reason – same hook semantics as the agent host; smoke: pp-remote –serve –mock-script: GET / renders the Nopales chat page; POST /chat streams multipart/mixed, chunked-framed, terminates promptly (scripts/smoke_remote_surface.sh)*

THE SEAM. The loop lives in llm/ (a shared package sibling of lisp/ and common/): provider.ml is a pure-OCaml OpenAI- compatible HTTP client (no image coupling), loop.ml is the turn orchestration factored over a small [Loop.host] record (tool_order, tool_entry, fire, eval_tool_body, call_prim), tools.ml is the builtin read/bash bodies with an explicit resolve_path + register. The agent links the same library and supplies Runtime.loop_host; pp-remote supplies Remote.loop_host over the proxy rim. ONE loop, two hosts – "agent/ is the local-only instance; pp-remote is the relaxed instance" is literally true in the code, not just in this spec.

THE KEY IS A VALUE. Provider credentials are client-side values: AGENT_API_KEY / AGENT_BASE_URL / AGENT_MODEL (the same env the agent binary reads; ./.env auto-loads; –mock-script substitutes a canned provider for tests/demos). No server round trip, no server-held secret. The provider call runs on the client machine; the corpus + data plane stay on the image.

WHAT CROSSES THE WIRE. Only Prim_call. A plugin tool's body evals under the proxy rim, so (get 'user id) inside a tool crosses to /api/prim exactly as a REPL eval would. Builtin tool bodies (read/bash) are OCaml prims in the LOCAL table – zero wire. (on "tool_call" ?) hooks and register-tool plugins work identically to the agent host, so plugin sources transfer between the hosts.

THE SURFACE. / is the chat page (Nopales-authored; the chat/* fragment templates carry the same names/shapes as the agent's surface so a restyle transfers); POST /chat streams multipart/mixed htmx parts from the same emitter shape the agent serves. The eval box moved to /eval; /code stays the lens browser. session/last-turn-parts captures a consumed turn's parts for hyper/stream replay, as on the agent.

V0 POSTURE. A chat turn holds the request mutex for its whole lifetime (single-user local harness – other tabs park until the turn finishes). The agent interleaves via its per-eval lock; the client has no eval mutex yet. Filing, not fixing.

hard-constraints

Constraints that are correctness, not v0 limitations – do not relax them

[status: implemented]

TRANSACTIONS DON'T SPAN PRIM CALLS. (with-transaction ?) holds (select-for-update ?) locks across prims in its body. Locks cannot survive an HTTP round trip. Any transaction-wrapped expression MUST execute server-side (placement forces /api/eval). Relaxing this corrupts the store.

CLOSURES DON'T CROSS THE WIRE. VLambda/VPrim serialize to a sentinel and do not round-trip. A server function invoked remotely returns a sentinel, not a callable. This is why function resolution is data (def source fetched and eval'd locally into the env), not RPC-into-a-closure. The proxy rim never tries to call a remote closure.

VERSION SKEW IS THE TAX. The corpus outlives the interpreter by design (defs are durable; the interpreter is a library that rebuilds). A story for "branch pinned to Nopales-semantics vN" is required once the corpus is the product: either semantics versioning in the env, or a migration lane when lisp/ changes behavior. poohstack "everyone rebuilds on switch" works for devs; it will not work for durable multi-version corpora.

IDENTITY IS SERVER-ASSERTED. The client passes basic-auth; it may not claim an author. whoami/current-author attach to the live session server-side and are returned BY the server, never set BY the client.

v0-non-goals

Explicit exclusions for the first remote-eval version

[status: implemented]

OUT for v0, deferred: - Browser/WASM client. Pulling defs from the server and executing them locally is fine for YOUR OWN corpus; it is a trust boundary the moment branches are multi-user. Later, with a capability model, not now. - Client-side caching of data_rows (only defs + read-heavy config rows are cached in v0). - Server-side caching of client state. The server keeps the corpus and the data plane; it does not memoize per-client. - A second transport. HTTP+JSON is the only wire in v0; no binary protocol, no websocket prim channel.

HARD OUT (within remote-eval; RESOLVED in-book by local-first.borg): - A second store on the client. In REMOTE-EVAL (the online mode) the client is a cache and an interpreter, never a source of truth. The offline mode this

hard-out appears to forbid is NOT a different project – it is local-first.borg, same book, same Prim_call seam: a LENS is a governed branch of the one tree with merge semantics (three-way tree-diff, branching.borg), not an uncoordinated copy. The hard-out still stands for exactly what it was written against: an UNCOORDINATED client copy. remote-eval and local-first are two policies of one seam (local-first.positioning): the data plane crosses the wire per-hit online, or resolves against the local lens offline and syncs on reconnect. The reframing is honest only because the one tree + three-way tree-diff merge already exist; without them this hard-out stays hard.) - Multi-user on the client. One client = one user. - Language changes made in remote/ instead of through lisp-interpreter.borg. The client is a host, not a fork.

11 borge/local-first.borg

pricklypear-local-first

Pricklypear book chapter: local-first – a local lens is a branch of the one tree whose root lives on the client. The pad detaches, roots independently, and grafts back. This revisits remote-eval's 'no second store on the client' hard-out: the hard-out was written against an uncoordinated client copy; a lens is a governed copy whose merge semantics already exist (three-way tree-diff, branching.borg / one-tree.branching-interaction). Same Prim_call seam, same tree, different lens policy.

[status: planned]

> – *agent note:* 2026-08-14 chapter created from the local-first design discussion. Thesis: one-tree + user-owned data + three-way tree-diff merge are, almost without addition, the local-first primitives. The 2026-08-02 /data revision (data.u.<user>.*) was made for multi-user isolation and turns out to also fix the replication unit – the isolation boundary and the replication boundary are the same shape. remote-eval is the online-remote mode (local compute, remote data plane); local-first is the offline-capable mode (local lens, sync on reconnect). One seam, two policies. The cactus metaphor (pads = lenses, grafting = merge, pads = lenses, grafting = merge) is evocative but is NOT load-bearing in this spec text – it lives in prose, not the source of truth. (2026-08-29 NAMING UPDATE: 'glochid' is RESERVED for the local-first harness itself – the detachable spine you pull off the pad and work with; see borge/agent.borg. The conflict work this note once called glochids is named sync-conflicts below, no metaphor.)
>
> 2026-12 campaign 8.0 plan pass: lens-model + replication-units pinned for the 8.1 make (details CONTRACT blocks below). A lens = a CHILD BRANCH of the checked-out branch via (fork) / Store.fork_branch (P5 empty-lens fork); the server branch stays the parent; single-writer-per-lens pins to the branch model; code sync = branch-pointer move (promote/merge), data sync = in-place reconcile. Replication unit = data.u.user, data.shared, b.lens plus branch ancestry; path-prefix RLS confinement is the replication boundary. Sync-negotiation handle = the branch,generation coordinate – the same migration-017 branch_generations / gen-now clock remote-eval.caching already keys on (one counter, three consumers). Status stays planned; the 8.1 make flips.

local-first

A client process that holds a durable local lens of the one tree, evaluates Nopales against it offline, and reconciles with the server on reconnect. The server keeps the corpus, the data plane authority, and the merge index; the client keeps a working copy and the interactive surface. Single-user per client; the server stays multi-user.

positioning

What local-first is and is not, relative to remote-eval, one-tree, and branching

[status: implemented]

IS: - A MODE of the Prim_call seam and the one tree, not a new product. remote-eval proxies DB prims over HTTP to a remote store; local-first resolves them against a LOCAL lens and syncs the lens on reconnect. Same interpreter, same rim abstraction, different backing for the data plane between syncs. - A BRANCH OF THE ONE TREE whose root lives on a client. This is what

reopens remote-eval's "no second store on the client" hard-out honestly: the hard-out was written against an UNCOORDINATED client copy (a second source of truth with no merge semantics). A lens is a GOVERNED copy – it is a branch, and branches already have merge semantics (branching.borg three-way tree-diff). The lens is not a second store; it is a remote branch of the one store. - The generalization remote-eval was deliberately scoped NOT to be. remote-eval's v0 is online-remote (local compute, every DB hit crosses the wire); local-first is offline-capable (local lens, DB hits resolve locally until sync). The placement heuristic (remote-eval.placement) is shared: pure compute stays local in both; the difference is whether DB reads cross the wire per-hit (remote-eval) or read the local lens (local-first) until reconnect.

THE USER LOOP, IN ONE BREATH. Fork locally (lens-model), evaluate against the local lens (local-substrate), sync in the background on reconnect (sync). "Invisible" is the property of the COMMON CASE – disjoint edits union cleanly and the user never sees the machinery. It has ONE designed exception: when the SAME node was edited on both sides since the last sync, the divergence is SURFACED (sync-conflicts), never silently resolved. The obituary rule (habitat-workflow) applies to sync losses.

IS NOT: - A second source of truth. The lens is a branch; the server is the integration point and the merge authority. Quit all clients; the server's tree is whole. - A Nopales fork. Same interpreter, same reader, same special forms (inherited from remote-eval.substrate and lisp-interpreter.borg). - Multi-user on the client. One client = one user's lens. - A relaxation of single-writer-per-lens. Each client is the SOLE writer of its own lens. Multi-writer reappears only at MERGE – exactly where three-way tree-diff already lives. This is git's argument, and it holds here.

lens-model

A local lens is a branch checked out to a client root. Fork = a pad detaching; sync = grafting back. Single-writer is preserved per-lens.

[status: implemented]

A CLONE IS A FORK. Checking out a local lens forks the user's current branch into a client-owned lens (e.g. admin/personal -> admin/laptop-2026-08-14). The fork is a branch like any other: a pointer into the one tree (one-tree.branching-interaction). The client materializes the lens subtree to its local substrate (filesystem – see local-substrate) and evaluates against it.

SINGLE-WRITER PER LENS, PRESERVED. The one-tree invariant ("one unix image serializes structural mutation; no merge-on-write races inside a commit") is preserved PER LENS. Each client is the sole writer of its own lens, so local writes need no concurrency machinery – a write is a local commit, atomicity is the substrate's. Multi-writer reappears only at SYNC, when the lens merges back to the server branch. That is exactly where three-way tree-diff (branching.borg, one-tree.branching-interaction) already lives. Local-first does not invent a new concurrency model; it adds a second site for the existing merge operation.

THE MERGE IS AUTOMATIC AND INVISIBLE IN THE COMMON CASE. "Each clone is its own branch" and "constant merges" are the SAME model, not alternatives – the branch is what makes the merges safe, and the merges are cheap because a solo user's lens rarely conflicts with its own server branch: - DATA is append-mostly and single-writer per user: a new todo on the laptop and a new todo on the server are disjoint nodes; the merge is a clean union, not a conflict. - CODE on a personal garden is effectively single-writer: you are the only editor of your own defs. A merge is a fast-forward unless you edited the SAME def on two devices before syncing – the rare, real conflict. The branch is a CORRECTNESS MECHANISM, not UX ceremony. The user's mental model is "my branch, synced across my devices"; fork-on-clone and merge-on-sync are implementation.

MULTI-DEVICE = STAR TOPOLOGY. Each device is its own lens (admin/laptop, admin/phone, ...) rendezvousing at the server branch (admin/personal) and the user's data subtree (data.u.admin). The server is the integration point. This is the simplest multi-device topology and it falls out of the branch model without addition.

CODE VS DATA SYNC POLICY. The one tree has two storage shapes, and they sync slightly differently – same algorithm (three-way tree-diff over subtrees, keyed on node hashes), different landing policy: - CODE (b.<branch>.{fn,type,route,pkg}.*) is branch-scoped. A clone forks a code lens; sync merges lens -> server branch by moving the branch pointer (the existing promote/merge primitive, branching.borg). - DATA (data.u.<user>.<type>.<id>) is user-owned and BRANCH-FREE (the 2026-08-02 /data revision). There is no branch pointer to move; sync reconciles the user's data subtree in place against the server's copy, server-mediated. data.shared.* is read-mostly seed; clients pull it but propose merges into it (the existing "explicit copy/move into data.shared" rule), preserving server-sole-writer for shared content. One algorithm, two policies for where the merged result lands. Both are subtree hash-diff + reconcile; neither invents a new primitive.

PLAN PASS (campaign 8.0, 2026-12) – lens fork CONTRACT pinned for the 8.1 make. A lens being "a branch checked out to a client root" is made concrete as a CHILD BRANCH of the checked-out branch: - FORK SURFACE. A clone forks the user's current branch into a client-owned lens via the EXISTING (fork ...) primitive / Store.fork_branch (branching.personal- workspace, one-tree P5 EMPTY-LENS fork – copy-on-fork, parent pointer only). The lens is an empty child of the checked-out branch; the server branch stays the parent. Naming: <owner>/lens-<device>[-<date>] (e.g. admin/personal -> admin/lens-laptop-2026-08-14). - MATERIALIZE. The client materializes the lens to its local substrate (local-substrate) and evaluates against it: local DB prims resolve against the lens files; the server is only the merge/index authority. - SINGLE-WRITER PER LENS, PINS TO THE BRANCH MODEL. The server NEVER writes into a client lens except via sync/ merge. Local writes are commits on the lens; atomicity is the substrate's (rename(2)). The branch is what makes the merges safe – no new concurrency model. - LANDING POLICY (pinned). CODE sync merges lens -> server branch by moving the branch pointer (the existing promote / merge primitive). DATA sync reconciles the user's data subtree IN PLACE against the server's copy (data is branch-free; there is no pointer to move). Both are subtree hash-diff + reconcile; neither a new prim.

> *[verify] build: dune build @all; smoke: lens/fork + remote/lib/lens_store.ml fork_lens_name name a lens branch <owner>/lens-<device>[-<date>] as a NAMED CHILD of the checked-out branch (empty-lens fork: parent pointer only, zero own rows, resolves through ancestry); smoke: the fork is single-writer; the server branch stays the parent (verified: lens-branch parent_id = checked-out branch)*

replication-units

What travels to a client: the user's data subtree + the checked-out code lens. The isolation boundary IS the replication boundary.

[status: implemented]

THE /data REVISION EARNS ITS SECOND SALARY. The 2026-08-02 user-owned data placement (data.u.<user>.* + data.shared.*) was made to fix MULTI-USER ISOLATION – a session sees only its own data.u.<user> plus data.shared. It turns out to also fix the REPLICATION UNIT: the subtree a client replicates is exactly data.u.<user>.* (that user's rows) plus data.shared.* (the read-mostly seed). The isolation boundary and the replication boundary are the SAME SHAPE – not a coincidence, but the tree being honest about ownership. A subtree scoped to one user for reads is the right subtree to copy to that user's device.

WHAT A CLIENT REPLICATES: - data.u.<user>.<type>.<id> – the user's own data (full) - data.shared.<type>.<id> – shared/seed content (read-mostly) - b.<lens>.{fn,type,route,pkg}.* – the forked code lens NOTHING ELSE. Another user's data.u.<other>.* never replicates to this client – not by a policy added for local-first, but by the path-prefix confinement that already governs reads (one-tree RLS floor). The client cannot ask for, and the server cannot send, a subtree the client's identity cannot read. Replication is authorized reads, batched.

CODE LENS SCOPE. The code lens replicated is the forked branch and its ancestry (defs resolve through inheritance, branching.borg). A client checking out admin/personal replicates personal's overrides plus the system/main ancestry they resolve through – the same env a server-side eval would build, materialized locally. Inheritance is read-time resolution (one-tree tree-model); the client stores the pinned overrides and resolves ancestors per the cache policy (remote-eval.caching generalizes).

NO CROSS-USER REPLICATION. Because replication is the authorized-read subtree, a compromised client that replays its sync token cannot exfiltrate another user's data – it can only request what its identity could read in a normal session. The trust boundary for local-first is the SAME trust boundary the online session already has, restated as "what subtree may replicate." This is why local-first does not inherit a new leak surface from remote-eval's browser/WASM trust punt: the browser punt is about EXECUTING untrusted corpus code in a browser; local-first executes the user's OWN corpus on the user's OWN device, which is the trust relationship the online image already assumes.

PLAN PASS (campaign 8.0, 2026-12) – REPLICATION SUBTREE PINNED for the 8.1 make. The replication unit is exactly the authorized-read subtree: data.u.<user>.* the user's own data (full) data.shared.* read-mostly seed b.<lens>.{fn,type,route,pkg}.* forked code lens (pinned at fork) PLUS the branch ancestry the lens resolves through (the system/main + parent overrides a server-side eval of the lens would build – materialized locally per inheritance read-time resolution). NOTHING outside it. Path-prefix confinement (one-tree RLS floor) is the replication boundary; the client cannot ask for, and the server cannot send, a subtree the identity cannot read in a normal session. Replication is authorized reads, BATCHED.

SYNC-NEGOTIATION HANDLE (the coordinate the manifest exchange keys on). The client records the (branch, generation) it last synced at; that snapshot is the merge base. This is NOT a new counter – it is the SAME migration-017 branch_generations coordinate tree-time promoted to the head/gen clock (gen-now / Store.current_generation) and remote-eval.caching keys its def cache on. One counter, three consumers (def-cache freshness, reads-as-of-gen, last-synced merge base). A sync round negotiates (path, hash) manifests and offers (branch, generation) as the common ancestor.

> *[verify] build: dune build @all; smoke: replication/unit + remote/lib/lens_store.ml in_replication_unit materialize EXACTLY data.u.<user>.* + data.shared.* + b.<lens>.* + branch ancestry (path-prefix RLS confinement is the replication boundary; another user's data.u.<other>.* never replicates); smoke: image/test/local_first_prims_test.ml: lens/fork creates the empty-lens named child; replication/unit returns a well-formed manifest*

local-substrate

The filesystem as lens root. No second query engine; the server is the index.

[status: implemented]

THE FILESYSTEM, NOT SQLITE. A local lens is a directory tree of node-envelope JSON files, one file per node, at its path:

<lens-root>/ b.admin.laptop.fn.todo-get.json b.admin.laptop.type.note.json data.u.admin.todo/<uuid>.json data.shared.flash-deck/<uuid>.json

Each file is the node envelope from one-tree.tree-model ({v,kind,path,type,body,author,doc,hash,created_at, updated_at}). The filesystem IS the path index: subtree queries are read-

dir/find; uniqueness is the filesystem; the envelope is a JSON file. There is no engine to align with Postgres, no second schema, no second set of migrations – the thing the remote-eval hard-out was trying to prevent (a second store) does not arise, because the lens is not a store, it is a materialized subtree.

WHY NOT SQLITE. SQLite imports a second query engine, a second schema, and a JSON1-vs-jsonb semantic divergence that must be kept aligned with Postgres by hand. Its entire reason to exist – concurrent ACID over a shared file – is unused: a local lens has ONE writer (the client), so atomicity is rename(2) and there is no concurrency machinery to justify. SQLite is the answer for a system with concurrent local writers; this system has none.

THE VAULT IS ALREADY FILES. pp-sync ships libs/*.pp, /code serves PP_SOURCE_ROOT, backups are directory dumps. The filesystem substrate IS the vault format – a local lens and a pp-sync snapshot are the same physical thing. A lens is inspectable with cat, jq, grep, diff, git. This is the Smalltalk/Pharo filetree feeling, honest: the image as an inspectable directory.

THE SERVER IS THE INDEX. A local lens is a WORKING COPY, not a query engine. Indexed reads over the whole corpus (tree/find-by with a body predicate, rows with a filter, list-kind over a large type) route to the server – the remote-eval placement heuristic, inherited. The lens holds the working set (open notes, current todos, the def being edited); the server holds the index over the corpus. Pure compute and working-set reads stay local; analytical reads cross the wire. Offline mode degrades gracefully on the analytical axis (indexed queries unavailable) while staying full-power on the working-set axis – the right failure shape for offline.

SUBSTRATE INTERFACE, NOT SUBSTRATE MANDATE. The spec pins the interface (path-addressed node get/put/subtree-list + envelope + hash) and names the filesystem as the v1 substrate. A content-addressed blob store is the natural v2 once content-addressing lands in the tree proper (one-tree.tree-model "content-addressing later"); the interface is stable across that swap. SQLite is not a named future substrate – if a lens ever needs real local indexing, the answer is a content-addressed store or a remote call to the server's index, not a second relational engine on the client.

8.2 MAKE (campaign 8, 2026-12). The substrate interface (path-addressed get/put/subtree-list + envelope + hash) was already in lens_store.ml (8.1) ; this make COMPLETED the replication-unit coverage the local-substrate stanza names:

- CODE-LENS MATERIALIZATION. [materialize_code_node] writes a code-node envelope at its b.<branch>.<kind>.<name> tree path (kind in {fn,type,route,pkg}) carrying the evaluable def source (the (define ?) form) + doc, same one-tree envelope shape + content hash as datum nodes – so sync's three-way tree-diff keys on the same [hash] for code.

- ANCESTRY MATERIALIZATION (read-time inheritance). [record_ancestry] / [ancestry] store the self-first (closest-wins) branch chain (lens, parent, ?, system/main) as <root>/___ancestry.json – the SAME override order store.branch_chain / function_defs use. [resolve_def] walks it, returning the closest b.<branch>.<kind>.<name> envelope (None on miss) – offline read-time inheritance per one-tree tree-model, no server round trip.

- CLIENT WIRING (evaluates against the local substrate). remote/lib/remote.ml takes an optional [~lens_lookup] (substrate def source); when set, [fetch_def] resolves FROM THE SUBSTRATE FIRST and only proxies [function-source] on a miss – the offline-first def path of the lens-model materialization.

- (PATH, HASH) MANIFEST. [node_manifest] walks the lens root and returns every node's (tree path, envelope hash) – the exact manifest the sync stanza's exchange negotiates on.

NOT in this make (kept open, owned by the sync stanza): the bidirectional manifest exchange + three-way merge against the server (image/lib/sync.ml, the actual-8.3 make). Local-first is not shipped end-to-end until 8.3 lands; this closes the substrate's own coverage so 8.3 diffs against a complete manifest

source.

> *[verify] build: dune build @all; smoke: remote/test/lens_store_test.ml: the local-substrate group (path_to_file, materialize_and_get, put_body_hash, subtree_list, code_kind_path, materialize_code_and_resolve, node_manifest, lens_fetch_first) – 10/10 green: code-lens nodes materialize at b.<branch>.<kind>.<name> with an evaluable src; ancestry records + round-trips self-first chain; resolve_def is closest-wins (a lens override beats its ancestry copy) and inherits a def present only on ancestry; the (path, hash) manifest lists every node (code AND datum) and excludes the ___ancestry metadata; Remote.fetch_def consults the substrate FIRST (a transport that raises is never touched on a substrate hit)*

sync

Sync = three-way tree-diff (branching.borg / one-tree.branching-interaction), keyed on subtree node hashes. The exchange is the git protocol in miniature.

[status: implemented]

> *[verify] doc: Sync = the server-side merge authority over tree_nodes, keyed on the same subtree node content hash the client lens substrate computes offline (one-tree.tree-model) – ONE hash scheme, both sides. image/test/sync_test.ml covers the pure core: manifest classification (same / client-only / server-only / diverge = the exchange's conflict DETECTION at node granularity) and the three-way merge planner (base = last-synced, ours = server, theirs = client) with every outcome (unchanged, theirs_add, ours_add, theirs_mod, ours_mod, identical, conflict, theirs_del, ours_del) + the actionable subset + JSON rendering. The sync/plan prim surfaces server_manifest / classify / plan_of (with an optional last-synced base manifest – the tree-time gen coordinate as merge base). The DB-backed harness (server_manifest / apply_client_node / commit) is exercised per the coexistence / deployment passes.*

ONE ALGORITHM, ALREADY SPECIFIED. Sync is the three-way tree-diff that one-tree.branching-interaction already plans for promote/merge. Subtree content hashes (one-tree.tree- model: hash over canonical body, root hashes compose from leaves) give CONFLICT DETECTION at node granularity. Generation counters (remote-eval.caching) generalize from one-way cache invalidation to bidirectional sync negotiation. Nothing new is invented: local-first sync is the merge primitive with a second consumer.

THE EXCHANGE. A sync round is the git protocol in miniature: 1. Client sends its (path, hash) manifest for the lens subtree(s). 2. Server compares against its own subtree hashes; reports which paths differ or are missing on each side. 3. Each side sends the node BODIES (envelopes) the other is missing or has stale. 4. Server applies the three-way merge (common ancestor = last-synced generation) and returns the merged subtree state; client applies the same merge locally. The envelope hash is the negotiation; the file is the transfer. No second query engine in the loop.

CODE SYNC. The forked code lens (b.<lens>.*) merges to the server branch (b.<user>.personal) by moving the branch pointer – the existing promote/merge primitive. Single- writer per user's personal code means this is usually a fast forward; conflict only on the same def edited on two devices.

DATA SYNC. data.u.<user>.* reconciles in place against the server's copy (no branch pointer – data is branch-free). Append-mostly user data means disjoint new nodes union cleanly; conflict only on the same node edited on two devices. data.shared.* is pulled (server-sole-writer); client proposals into shared go through an explicit merge-request, not direct write.

LAST-SYNCED AS THE COMMON ANCESTOR. Three-way merge needs a common ancestor. The client records the (branch, generation) it last synced at; that snapshot is the merge base. This is the remote-eval.caching generation

counter, repurposed from "is my cache fresh" to "what was our last common state." One counter, two uses.

SHIPPED V1 TRANSPORT (data paths, 0bebd9a). The exchange is no longer only a planned protocol: the sync/push prim (image/lib/prims_db.ml) classifies a client data.u.<user>.* (path, hash) manifest against the server, applies ClientOnly pushes through Sync.apply_client_node (the typed-boundary-validated datum write surface; image/test/sync_db_test.ml), returns ServerOnly paths for the client to pull, and REPORTS diverge paths without auto-merging them (sync-conflicts stance: v1 surfaces, it does not silently resolve). pp-remote –sync (remote/bin/main.ml) drives the round – push, pull server-only paths, print DIVERGE lines, and pin the returned (branch, generation) as the next merge base.

CODE-LENS SYNC STAYS THE BRANCH-POINTER MOVE. b.<lens>.* is deliberately OUT of sync/push's scope: code sync merges lens -> server branch via the existing promote/merge primitive (branching.borg), server-mediated. Data sync is in-place reconcile; code sync is a pointer move – one algorithm family, two landing policies, as lens-model pins.

"BACKGROUND" IS CLIENT SCHEDULING, NOT NEW MACHINERY. Sync is round-based; –sync is the manual v1 entry point. Making it invisible is the client invoking rounds on reconnect / on a timer against the same prims – no new server surface is needed or planned for it.

sync-conflicts

The honest open work: conflict RESOLUTION policy, offline identity, semantics skew, transactions-under-sync. Detection is free; resolution is not.

[status: planned]

THE TREE DETECTS; IT DOES NOT RESOLVE. Subtree hashes give node-granular conflict DETECTION (these two nodes diverged since the common ancestor). They do not give a RESOLUTION policy. Naming the policy is the real research-shaped gap – the pads graft easily most of the time; the conflicts bite at sync. Candidates, in increasing ambition: - LAST-WRITER-WINS per node (updated_at arbitrates). Cheap, loses concurrent edits to the same node. Acceptable for data where the rare same-node concurrent edit is a user error anyway. - SEMANTIC MERGE per type (a type declares its merge strategy: todo status is LWW, note body is three-way-text-merge, a counter field is sum). Uses one-tree typed-nodes – the type declaration carries the merge policy. Most honest; most work. - CRDT-ISH field types for hot fields (a counter that sums, a set that unions). Opt-in per field via the type declaration. Heaviest; only where worth it. v0 is LWW-per-node with a conflict SURFACED to the user (no silent loss – the obituary rule, habitat-workflow, applies to sync losses too). Semantic merge is the v1 ambition and the place typed-nodes earns a third salary.

OFFLINE IDENTITY. remote-eval: "identity is server-asserted, never client-asserted." Offline edits must assert author locally and reconcile at sync. The per-node author field + branch ownership give the audit trail; the mechanism is durable client credentials (a signed sync token / device key) presented at sync, with the server asserting the identity onto the merged nodes. The client never CLAIMS an author it does not hold – it stamps its credential; the server validates and attributes. This is a real trust- boundary change from online (where the session asserts per request) and it inherits remote-eval's browser/WASM trust punt as an open question for untrusted-client execution.

SEMANTICS VERSION SKEW. remote-eval hard-constraint already flags "a story for branch pinned to Nopales-semantics vN is required once the corpus is the product." Local-first makes it acute: an offline client runs old interpreter semantics against a corpus that may have evolved at sync. The lens pins a (branch, generation, semantics-version) snapshot (remote-eval.stepping's "pin a snapshot and replay" is the substrate). At sync, a semantics-version mismatch is a merge-gate event: the client must rebase to the server's semantics before

merging edits, or the server re-evaluates the client's def source under current semantics. The honest rule: defs are durable DATA (source), so the server can always re-eval a client's def source under current semantics – the skew is in BEHAVIOR the client observed offline, not in the source. Behavior skew is surfaced, not silently merged.

TRANSACTIONS UNDER SYNC. Online, the remote-eval hard constraint stands: (with-transaction ...) holds (select-for-update) locks that cannot span HTTP, so transaction-wrapped exprs execute server-side. Offline, the client is sole writer of its lens – local transactions work as-is (single writer, locks trivial, the lens substrate provides atomicity via rename). At SYNC, concurrent local transactions become MERGE CONFLICTS, not lock contention – the hard constraint MOVES, it does not vanish. It stays true online; offline it becomes a merge problem this subsection owns. A transaction that must be atomic across sync (rare – most txns are within a single editing session) is surfaced as a conflict on all its constituent nodes rather than silently partial-merged.

STATUS (reconcile after 0bebd9a): DETECTION IS SHIPPED, THE v1 DATA TRANSPORT IS SHIPPED, RESOLUTION IS DELIBERATELY NOT. Campaign 8.3 (sync subsection, implemented) delivered the node-granular divergence detection this subsection's thesis names: image/lib/sync.ml manifests path,hash deltas, classifies them, and three-way-merges (base = last-synced generation, ours = server, theirs = client) to a plan whose conflict outcome is surfaced REPORT-ONLY. The transport the previous reconcile called "not yet built" then landed in 0bebd9a: sync/push (image/lib/prims_db.ml) + pp-remote –sync (remote/bin/main.ml) – a two-way, data-only round that applies client-only pushes, pulls server-only paths, and REPORTS diverge paths with the server copy kept. That report IS the v1 conflict stance, and it is deliberate, not a gap in the transport: no automatic LWW arbitration of a same-node divergent pair – v1 surfaces honestly rather than silently clobbering. What remains genuinely open here is the RESOLUTION POLICY menu above (LWW-per-node as an APPLIED policy, semantic merge per type, CRDT-ish fields), OFFLINE IDENTITY (durable device-signing credential presented at sync), SEMANTICS VERSION SKEW (lens-pinned semantics snapshot + sync-time rebase/re-eval gate), and TRANSACTIONS UNDER SYNC (conflict surfacing for cross-sync txns). Subsection stays planned; the open work is resolution + identity + skew + txns-under-sync, not detection and not the v1 data transport.

phasing

Read-only offline first (achievable, defers the conflicts); write-capable lenses with automatic merge second

[status: planned]

PHASE 1 – READ-ONLY OFFLINE. A client pins a (branch, generation) snapshot, materializes it to the filesystem lens, and evaluates read-only against it offline. No local writes; on reconnect, the client re-syncs the snapshot (cheap – discard and re-pull, since it made no edits). This is much closer to shipped: it reuses remote-eval.caching's generation pin and the filesystem substrate, with NO merge machinery. It delivers most of the local-first FEEL (no spinners on reads, offline read access, instant open) without the merge-conflict policy. The debugger substrate (remote-eval.stepping) works against a read-only lens unchanged.

PHASE 2 – WRITE-CAPABLE LENSES. Fork-on-clone, local writes, automatic merge on sync (lens-model + sync). LWW-per-node conflict resolution with surfaced conflicts (sync-conflicts v0). This is the full local-first design. The hard problems (semantic merge, offline identity, semantics skew) mature within phase 2, not before it.

NOT A PHASE GATE. Phase 1 is a shippable milestone, not a prerequisite – the phase 2 design does not depend on phase 1 being shipped first. But phase

1 is the honest first cut because it defers the one piece of real research (conflict resolution policy) while delivering the working-copy feel.

STATUS (reconcile after b15a06a + 0bebd9a): BOTH FLOWS NOW EXIST AS pp-remote ENTRY POINTS – MANUAL v1, NOT YET BACKGROUND. Phase 1's "user-facing read-only offline flow" the previous reconcile called unshipped exists: pp-remote –lens DIR + –lens-pull materializes a lens and evaluates offline-first against the substrate. Phase 2's "transport not yet built" also landed for DATA: sync/push + pp-remote –sync (0bebd9a) close the write loop – local eval, tree to disk, push up, pull down, diverge surfaced, new (branch, generation) merge base pinned. What is NOT yet shipped: (a) sync as an AUTOMATIC background/on-reconnect loop – today it is user-invoked (–sync); the scheduling is client-side and needs no new server machinery, but the loop itself is unbuilt; (b) code-lens sync through the exchange – b.<lens>.* syncs via the server-mediated promote/merge pointer move, a separate path sync/push deliberately excludes; (c) sync-conflicts resolution POLICY (v1 reports diverge; nothing auto-resolves). Subsection stays planned; the open work is the background loop + the resolution policy, not the transport and not the flows.

non-goals

What local-first is NOT

[status: implemented]

- NOT a second store. The lens is a branch of the one tree; the server is the integration point and merge authority. - NOT multi-user on the client. One client = one user's lens, same as remote-eval. - NOT a Nopales fork. Same interpreter, same reader, same special forms (remote-eval.substrate). - NOT a relaxation of single-writer-per-lens. Each client is sole writer of its own lens; multi-writer appears only at merge. - NOT automatic conflict RESOLUTION. The tree DETECTS conflicts (hashes); resolution is a policy (sync-conflicts). v0 surfaces; it does not silently resolve. - Data lens versioning (IMPLEMENTED v0, 2026-08-23 make). data.u.<user>.* stays single-head and branch-free (this property is preserved). An opt-in data.l.<lens>.<user>.* namespace adds deliberate data forks that diverge and merge back via LWW (v0; three-way tree-diff is v1). The local-first lens materializes and syncs the user's data subtree; the data lens fork makes that first-class. - NOT a second transport. HTTP+JSON is the only wire in v0 (inherited from remote-eval). The filesystem is the local substrate, not a wire. - NOT a browser/WASM client. Executing a user's corpus in a browser is a trust boundary local-first inherits from remote-eval's punt and does not reopen; local-first runs on a client the user controls (laptop, phone), where the trust relationship is "my code on my device."

12 borge/storage.borg

pricklypear-storage

Pricklypear book chapter: storage
[status: implemented]

– *agent note:* 2026-08-02 status reconcile: all section children implemented/verified (schema, no-inheritance, transactions, with-transaction, media); lift project.

storage

Postgres schema: branches, function_defs, type_defs, data_rows. SERIALIZABLE defaults. NO inheritance.
[status: implemented]

schema

Core tables (in migrations/001_branches.sql)
[status: implemented]
– The shared code store CREATE TABLE branches (id uuid PRIMARY KEY, parent_id uuid REFERENCES branches(id), owner text NOT NULL, name text NOT NULL, created_at timestamptz NOT NULL DEFAULT now(), last_synced timestamptz, – for merge diffing UNIQUE (owner, name));

CREATE TABLE function_defs (branch_id uuid NOT NULL REFERENCES branches(id) ON DELETE CASCADE, name text NOT NULL, body jsonb NOT NULL, – serialized Nopales AST doc text, author text NOT NULL, updated_at timestamptz NOT NULL DEFAULT now(), PRIMARY KEY (branch_id, name));

CREATE TABLE type_defs (branch_id uuid NOT NULL REFERENCES branches(id) ON DELETE CASCADE, name text NOT NULL, fields jsonb NOT NULL, – field declarations migrated bool NOT NULL DEFAULT false, schema_vers int NOT NULL DEFAULT 1, author text NOT NULL, updated_at timestamptz NOT NULL DEFAULT now(), PRIMARY KEY (branch_id, name));

CREATE TABLE view_bindings (branch_id uuid NOT NULL REFERENCES branches(id) ON DELETE CASCADE, route text NOT NULL, – e.g. "/inspect/:id" handler text NOT NULL, – function name PRIMARY KEY (branch_id, route));

CREATE TABLE sessions (id uuid PRIMARY KEY, user_id text NOT NULL, branch_id uuid NOT NULL REFERENCES branches(id), pid int, – image instance pid boot_mode text NOT NULL, – 'on-connect'|'always' health text NOT NULL DEFAULT 'unknown', started_at timestamptz NOT NULL DEFAULT now(), last_seen timestamptz); – LEGACY/INERT: process bookkeeping from the – retired fleet design. The image never reads or – writes it. Kept because migrations are – additive-only.

– All Nopales-declared types share ONE table, – data_rows (migration 003), keyed by – (type_name, id) with fields packed as jsonb. – There are no per-type tables; deftype emits no – DDL. data_rows is NOT branched.

CREATE TABLE schema_migrations (version int PRIMARY KEY, applied_at timestamptz NOT NULL DEFAULT now(), description text);

The shared data_rows table lives alongside these system tables (migration 003; see object-model).

SERIALIZABLE is the transaction isolation default for ALL Nopales-driven mutations. Weaker isolation is opt-in per query.

> *[verify] build: dune build @all; build: psql -f migrations/00{1,2,3}*.sql applies clean on a fresh database; smoke: image applies migrations on boot (see image/lib/session.ml boot sequence)*

no-inheritance

Why we do NOT use Postgres INHERITS

[status: implemented]

Postgres table inheritance (INHERITS) is the deprecated feature from the early-90s Postgres implementation. We deliberately do NOT use it.

THE CORE REASON: branches are an OVERRIDE primitive, not a UNION primitive. When Alice forks and overrides 'greet', her branch's view should see ONLY her greet, not main's greet merged in. Postgres inheritance does union (both rows visible), not override.

Modeling override on top of inheritance forces us to write override resolution ourselves anyway (pick the child's row when it exists), so inheritance buys nothing but its quirks.

Other reasons: - Foreign keys / unique constraints don't span inheritance trees properly - PRIMARY KEY doesn't propagate - The planner handles inherited queries with edge cases and unpredictability - Inheritance handles schema evolution (add/remove columns) inconsistently; migrations would be a horror show - pg_dump, psql, admin tools render inheritance weirdly - We'd pin ourselves to non-standard semantics

Plain tables with branch_id FK and override resolution in queries (recursive CTE up the parent chain, or materialized effective-definition) gives us: - Clean indexed SELECTs - Predictable planner behavior - Standard migrations - Full inspectability (the goal) - A clean path to content-addressing later if we want "actually git" semantics

Future options stay open. Inheritance forecloses them.

> *[verify] build: dune build @all; smoke: override-walk + branch isolation (closest-ancestor wins, parent unchanged)*

transactions

Transaction isolation: SERIALIZABLE by default

[status: implemented]

All Nopales-driven mutations run in SERIALIZABLE transactions by default. Postgres detects conflicts at commit and aborts one, forcing retry. For a multi-user personal OS, throughput is not the concern; correctness is.

Opt-in weaker isolation: (query ... isolation: 'read-committed) Available but discouraged. Most user code never touches this; the system does the safe thing by default. (v1.5 – the with-transaction prim already accepts the isolation arg shape, defaulting to SERIALIZABLE; the weaker-isolation passthrough remains additive when shipped.)

Explicit row locks: (select-for-update 'type id) Exposed as a primitive for finer control. Persists across subsequent prims in the same with-transaction body.

Cache coherence (initial): NO caching of stored function defs in image memory. Each call reads the AST fresh from Postgres. For a personal OS where most calls are query+render, the function read alongside the query is acceptable overhead.

Cache coherence (later): LISTEN/NOTIFY-based invalidation. When a function is updated, the updating image notifies; others drop from cache. Mechanism well-trodden, deferred until measured.

> *[verify] test: image/test/primitives_test.ml – 48 alcotest cases; build: dune build @all; smoke: duplicate-fork UNIQUE violation triggers pgx auto-rollback; smoke: fork_branch returns new branch id (str round-trip); smoke: merge_branch returns merged-rows count; smoke: (select-for-update 'type id) takes a row lock visible to concurrent transactions*

with-transaction

Dynamic transaction scoping: (with-transaction (lambda () body))

[status: verified]

Dynamic transaction scope: all DB prims called inside the body run against the SAME pgx transactional connection. Defaults to SERIALIZABLE isolation.

(with-transaction (lambda () (seq (select-for-update 'type id) (update-field 'type id "field" "value"))))

The select-for-update row lock PERSISTS across the subsequent update-field in the same body – this is the v1 concurrency-protection story for compound mutations.

Nested transactions raise a clean Interp_error. The body value is returned verbatim (no wrapper tags/boxing).

The Lambda body is evaluated lazily; the dynamic binding is set on ‘Store.t.current_tx‘ before the body runs and cleared via ‘Lwt.finalize‘ after (whether BODY succeeds or raises – pgx still sees the propagated exception and rolls back).

> *[verify] test: image/test/primitives_test.ml – 48 alcotest cases; build: dune build @all; smoke: with-transaction body runs its prims on one transactional connection; row locks persist across prims*

media

Binary media blobs in Postgres: agent upload + authenticated serve

[status: implemented]

WHY A SEPARATE TABLE (not data_rows jsonb) ———————————— data_rows packs field documents as jsonb. Binary payloads do not belong there: base64-in-jsonb wastes ~33% space, blows GIN indexes, and fights the 64 KiB /api/eval body cap that protects the Nopales path. Media is first-class storage – same "Postgres is the object store" thesis, different physical shape.

SCHEMA (migration 007_media.sql) ———————————— CREATE TABLE media_blobs (id uuid PRIMARY KEY DEFAULT gen_random_uuid(), author text NOT NULL, content_type text NOT NULL, filename text, – optional original name byte_size int NOT NULL, sha256 text NOT NULL, – hex digest of bytes data bytea NOT NULL, meta jsonb NOT NULL DEFAULT '{}', created_at timestamptz NOT NULL DEFAULT now(), updated_at timestamptz NOT NULL DEFAULT now()); CREATE INDEX media_blobs_author_idx ON media_blobs (author); CREATE INDEX media_blobs_created_idx ON media_blobs (created_at DESC); CREATE INDEX media_blobs_sha256_idx ON media_blobs (sha256);

Shared across branches (same rule as data_rows): fork/merge copies code, not media. Ownership is the author column + session identity, not branch_id.

AGENT PUSH (primary write path) ————————————- Agents MUST NOT push multi-KiB binaries through POST /api/eval (max_user_body_bytes = 64 KiB). Dedicated authenticated endpoints:

POST /api/media Auth: HTTP Basic or session cookie (same as eval). Body modes (Content-Type decides): 1. Raw binary – request Content-Type is the media type (image/png, image/jpeg, ?). Optional header X-Filename: original name. 2. JSON – application/json { "content_type": "image/png" , "data_b64": "?" , "filename": "shot.png" // optional , "meta": {?} } // optional Body limit for this route: 5 MiB (not the 64 KiB eval cap). Reject oversize with 413. MIME whitelist (v1): image/png image/jpeg image/gif image/webp image/svg+xml application/pdf On success 201: { "ok": true , "id": "<uuid>" , "content_type": "?" , "byte_size": N , "sha256": "?" , "url": "/media/<uuid>" , "filename": "?" | null } Errors: 400 bad args / bad b64 / disallowed type, 401 unauth, 413 too large, 500 store fail.

GET /media/<uuid> Auth required (private by default – same gate as /data). Serves raw bytes with Content-Type from the row, Content-Length,

Cache-Control: private, optional Content-Disposition inline; filename= when filename is set. 404 if missing.

DELETE /api/media/<uuid> Auth required. Author-or-admin may delete. 200 {ok,id} or 404/403.

GET /api/media (optional list) Auth required. JSON array of meta rows for the caller (id, content_type, byte_size, sha256, filename, author, created_at) – NO data bytes. Query: ?limit=N (default 50, max 200).

Client helper: scripts/pp_media.py python3 scripts/pp_media.py put ./shot.png python3 scripts/pp_media.py get <id> -o out.png python3 scripts/pp_media.py list python3 scripts/pp_media.py delete <id> Same env as pp_eval (PP_URL / PP_USER / PP_PASS).

LISP PRIMITIVES (meta + small ops; not bulk upload) ———————————— Registered next to CRUD. Anonymous denied on writes.

(media-meta id) -> VStr json | VNil id, author, content_type, filename, byte_size, sha256, meta, created_at, url – never the bytes.

(media-list [limit]) -> VList of meta json strings

(media-delete id) -> VStr id | VNil Author-or-admin; others get a denial string.

(media-put content-type data-b64 [filename]) -> VStr new-id | error string Convenience for TINY payloads that already fit eval (icons, test fixtures). Same whitelist + 256 KiB ceiling on decoded size so eval cannot be abused as a bulk pipe. Real agent pushes use POST /api/media.

(media-url id) -> VStr "/media/<id>"

No (media-get-bytes) over eval in v1 – serve via HTTP.

IMPLEMENTATION NOTES ———————— - image/lib/media.ml: store helpers (put/get/meta/ list/delete) over pgx; Pgx.Value.of_binary / to_binary for bytea; Digestif SHA256 hex. - image/lib/http_media.ml: route handlers; own body reader with max_media_body_bytes = 5 MiB. - Wire in http.ml dispatch; keep /api/media behind the normal auth middleware (NOT hard-public). - session.ml register_media_prims alongside CRUD. - agent_discovery.ml: document POST /api/media and pp_media.py in agent.json / agent.txt rules. - scripts/dev.sh migration loop: add 007_media. - migrations.borg applied-by-image list: 007.

NON-GOALS (v1) ————— - Public unauthenticated media URLs (later: flag or signed token if product needs it) - Per-user byte quotas (multi-user.budgets memory track stays deferred; soft 5 MiB/request is enough) - Image transforms / thumbnails / EXIF strip - S3 or filesystem offload (bytea in PG is the v1 habitat; hoist later if measured hot) - Dedup-by-sha256 on put (index exists; policy later)

> *[verify] build: dune build @all; test: image/test/media_test.ml – put/meta/list/delete + mime reject; smoke: scripts/dev.sh applies 007; POST /api/media with basic auth stores png; GET /media/<id> returns image/png bytes; smoke: python3 scripts/pp_media.py put <fixture.png> prints id; get round-trips bytes; smoke: POST /api/eval still capped at 64 KiB; media route accepts up to 5 MiB*

13 borge/multi-user.borg

pricklypear-multi-user

Pricklypear book chapter: multi-user – MANY HUMANS. Cotenant isolation (this chapter) is the shipping model: one process, many sessions, isolation by session + branch. Process-per-user isolation (multi-user.isolation) is a future hardening axis. single-image.borg is about shipping ONE binary, not one human. Do not read single-image as cancelling multi-user. Access surfaces that ship on cotenant first: user subdomains, per-user LLM keys, SSH?REPL (auth.user-subdomains / user-llm-keys / user-ssh-repl).

[status: partial]

> – *agent note:* 2026-08-02 status reconcile: namespaces/budgets/chat/user-plan ? implemented; permissions stays partial (setuid author). isolation deprecated; cotenant-isolation already implemented.

multi-user

Cotenant isolation (one process, session + branch scoped), namespaces via branch ownership, budgets, author-runs-as-author

[status: partial]

cotenant-isolation

Session-level isolation in one process – THE v1 model

[status: implemented]

One image process serves many authenticated sessions. Isolation is session + branch scoped, not process scoped:

- Each session carries its own identity (user_id, username, is_admin) resolved at login and attached per request. - Each session has its own default branch (<username>/personal); defines, routes, and type declarations land on the session's current branch. - No session writes to another user's personal branch; overrides on a personal branch shadow system/main only for that branch's readers. - Session state is not shared; a wedged call aborts its own session's work, not another user's.

What cotenant does NOT provide (honest limits): - No per-user process boundary: a hard process crash takes all sessions down together (the watchdog restarts the one image for everyone). - Resource contention is shared: one user's expensive eval competes with everyone else's (mitigated by per-session step budgets – see budgets). Per-user image processes (multi-user.isolation) remain the future hardening axis for a stronger blast radius.

isolation

Future hardening axis: process-level isolation, one image per user

[status: deprecated]

DESIGN SKETCH (not the shipping topology).

The retired fleet design gave each user their OWN image process rather than namespacing within one shared image – the Unix/POSIX model: each user has a home (their branch bindings); logging in boots or attaches their image; each image is a separate process.

Wins it would buy: a user's infinite loop or bad define wedges only their image; per-user A/B rollback; no reliance on cooperative scheduling for cross-user safety.

Why it is not v1: it needs a supervisor/fleet layer (boot-on-connect, attach, per-user RAM), which the single-image pivot retired. Cotenant isolation (above) is the shipping model; this remains the future hardening axis if a stronger blast radius is ever needed.

namespaces

Branch ownership namespaces; packages are a separate in-branch axis
[status: implemented]

TWO AXES (do not conflate):

1. BRANCH namespace (this subsection): There is no privileged 'common' namespace. There is 'main' (system baseline) and per-user branches. Versioning/ownership IS branch ownership. A binding's key is (branch_id, name). When Alice forks main to alice/main, she gets her own 'greet' independent of main's greet (until she merges).

2. PACKAGE prefix (image.packages): Within ONE branch, organize functions with '/' in the name (todo/list). That is organization, not ownership. See image.packages.

Cross-branch calls (still deferred): a function can explicitly reference another branch's binding via a qualified name (e.g. system/main:greet – note colon or other separator TBD, must not collide with package '/'). Normally a function calls bindings in its own branch.

The 'common namespace problem' is thus reframed as the 'merge to main politics problem': - Default: admin-only merges to main - All users can fork freely - Users can merge into their own branches freely - Politics expand later (PR/review workflow)

This sidesteps the up-or-down political decision the original 'publish to common' model forced.

> – *agent note:* 2026-08-02: branch ownership model live (system/main + user/*); package / prefix separate. Cross-branch qualified calls still deferred as documented.

budgets

Per-call step budgets to bound runaway user code
[status: implemented]

> – *agent note:* 2026-08-02: Eval.make_budget + last_budget; session eval wraps budget; conformance tests. Memory budget deferred.

> *[verify] build: dune build @all; smoke: a Nopales call that exceeds its step budget aborts cleanly; the session survives*

Each Nopales primitive invocation runs with a step counter. When exceeded, that ONE call aborts; the session continues. This prevents "one user's bad function wedges the whole image" at the interpreter level (defense in depth alongside process-level isolation).

Default budget: configurable per session, sensible initial value (e.g. 100k eval steps). User can request more for legitimate long-running operations via a primitive that explicitly raises the budget for a sub-call (and logs it).

The interpreter checks the counter at every Prim invocation and every recursive eval depth. Cheap: one integer increment per step.

Memory: also tracked. A session exceeding memory budget aborts the offending call. (Deferred; step budget is the v1 mechanism.)

This is per-CALL, not per-session: a session can make many calls, each independently bounded.

permissions

Author-runs-as-author: functions execute with their author's data perms
[status: partial]

A function executes with ITS AUTHOR's data permissions, not the caller's. This is the Unix setuid model: if alice authors a function that reads her calendar, and bob calls it, the function reads alice's calendar (not bob's), and bob sees only what alice's function returns.

Implications: - The interpreter's eval carries a (current-author) field, read from the EXECUTED binding's author, not the session user. - Data primitives (query, get, create, etc.) consult current-author for permission filtering. - A careless privileged function is a security hole, same as Unix setuid. Honest and familiar. - Functions can expose capabilities to other users by name without exposing raw rows.

Authoring permissions (separate concern): - A binding in alice/main is callable by anyone in the same image (read access implicit). - Only alice can edit bindings in alice/* branches. - main is owned by admin; merges require admin approval (default).

This model is the Unix model, by choice. It maps cleanly to "SSH-first, multi-user OS" framing. If we wanted a Lisp-machine feel (shared trusted environment), we'd pick differently, but SSH-first implies Unix-style multi-user.

SOCIAL LAYER (chat + plan) uses SHARED data_rows (existing storage rule) with handler-enforced filters by (whoami). That is intentional: messages and plans are multi-user objects, not personal-branch pins. Branch gardens stay code/UI; social state is rows. See multi-user.chat and multi-user.user-plan.

> – *agent note:* 2026-08-02 confirm partial: current-author still aliases whoami; full setuid author-on-execute not shipped.

chat

Multi-user chat: site lobby + DMs so humans on the box can talk
[status: implemented]

> – *agent note:* 2026-08-02: libs/chat ~552 lines lobby+DM; live GET /chat 200.

> *[verify] build: dune build image; smoke: alice and bob post to /chat lobby; each sees both messages; smoke: alice DM to bob visible to both; not to carol; smoke: unauth /chat redirects login; public face does not leak messages; smoke: (chat/say "hi") and (chat/inbox) work via /api/eval*

==========
0. WHY ==========

Multi-user is not only isolation – people on the same habitat need a way to talk. Chat is a first-class product surface (like notes/todo), not an external app. Agents authenticated as users may post too (same identity rules).

==========
1. SHAPE (v1) ==========

Two conversation kinds:

A. LOBBY (site-wide room) room_id = "lobby" (singleton) All authenticated users can read/write. Default /chat UI.

B. DM (direct message thread) room_id = canonical pair key: dm:alice:bob where alice < bob lexicographically Participants = the two usernames only. List/create from /chat/dm or (chat/dm "bob").

Out of scope v1: - Arbitrary named rooms / channels (phase 2) - WebSockets / SSE push (htmx poll is enough) - File attachments, reactions, threads, edit history - End-to-end encryption - Cross-deployment federation

==========
2. DATA (shared data_rows) ==========

Package libs/chat seeds:

(deftype 'chat-room 'kind ; "lobby" | "dm" 'room_id ; "lobby" | "dm:a:b" 'title ; display 'members ; JSON array of usernames; lobby = [] 'created_by 'created_at) ; ISO string from Nopales or server

(deftype 'chat-message 'room_id 'from ; username (whoami at post) 'body ; plain text (escape on render) 'created_at)

data_rows are SHARED across branches (storage rule). Access control is in chat/* handlers: - post: from MUST equal (whoami); reject spoof - list lobby: any authenticated user - list dm: whoami is member - create dm room: both users must exist

Retention v1: keep all messages (personal OS scale). Optional later: max list limit + archive.

Seed: ensure lobby room row exists on load-library (idempotent create-if-missing).

==========

3. LISP API (libs/chat) ==========

(chat/say body) ; post to lobby as whoami (chat/say-in room_id body) ; post to room if allowed (chat/lobby [limit]) ; recent lobby messages (chat/history room_id [limit]) (chat/dm peer) ; ensure dm room; return room_id (chat/dms) ; rooms where whoami is member (chat/users) ; list usernames (for DM picker) ; needs thin OCaml prim ; (list-usernames) for any authed

New OCaml prim if missing (image): (list-usernames) ? VList of VStr authenticated only; usernames are public identifiers on the box (no email/admin leak).

==========

4. HTTP / HTMX UI ==========

Routes (private by default – auth required):

GET /chat lobby page GET /chat/partial message list fragment (poll) POST /chat/say body=text ? append + refresh GET /chat/dm list DM threads GET /chat/dm/:peer DM thread with peer POST /chat/dm/:peer send DM

Polling: hx-get /chat/partial hx-trigger every 3s-5s. No WebSocket in v1.

Chrome: ui/nav link Chat when package loaded. Render: escape body text; show from + time + body. Empty state: Say hi to the box.

==========

5. SECURITY / POLICY ==========

- No anonymous chat (kernel private routes) - Body max length (e.g. 4k chars) enforced in chat/say - Rate: soft – eval budget enough for v1 - XSS: escape user body on render; never raw untrusted HTML - Spoof: ignore client-supplied from; always whoami

==========

6. PHASES ==========

Phase 1: deftype + lobby say/history + /chat UI poll Phase 2: DMs + list-usernames + /chat/dm Phase 3: nav seed, optional presence / unread

Success: two browser sessions (alice, bob) talk in lobby without leaving the habitat; agent as alice can (chat/say "deployed") visible to bob.

user-plan

Unix-style .plan: short per-user status of what they intend to work on

[status: implemented]

> – *agent note:* 2026-08-02: libs/plan user-plan + plan/set!/of; live GET /plan 200.
>
> *[verify] build: dune build image; smoke: (plan "macros + chat") sets alice plan; (plan-of "alice") returns it; smoke: GET /u/alice shows plan text; bob can read alice plan; smoke: only owner can set own plan; bob cannot set alice; smoke: empty plan shows friendly placeholder*

==========

0. WHY (finger / .plan) ==========

Classic Unix: each user has a ~/.plan file; finger(1) shows it. On a multi-user Lisp OS this is the lightest coordination tool – not a task tracker (todo exists), not chat, just what I'm working on / intend next.

Complements chat: plan is sticky status; chat is conversation.

==========

1. DATA ==========

(deftype 'user-plan 'username ; owner; unique logical key 'body ; free text (plain) 'updated_at) ; ISO string

One logical plan per username. Implementation: find existing row where username matches whoami; update body + updated_at, or create if missing. Shared data_rows; filter by username field.

Optional later: project / until date – not v1.

==========

2. LISP API (libs/plan) ==========

(plan body) ; set MY plan (whoami); return body (plan) ; get MY plan body or empty string (plan-of user) ; get that user's plan body or empty (plan-clear) ; set my body to empty (plan-list) ; list of (username . body) for ; users with non-empty plans

Spoof: (plan) always writes username=(whoami). There is no (plan-as other body).

==========

3. HTTP UI ==========

Private (auth required) unless noted:

GET /plan edit-or-view MY plan form POST /plan save body GET /plans directory: who has a plan set GET /u/:username profile stub: username + plan body + updated_at + link to garden subdomain if auth.user-subdomains on (finger alice)

Public option (phase 2, with route-visibility): public /u/:user so plans can be world-readable like classic finger. v1: authenticated users on the box only.

Chrome: show MY plan one-liner under whoami in header or on home (ui/home snippet) – optional phase 2. Nav: Plan ? /plan; People ? /plans.

==========

4. UX COPY ==========

Placeholder when empty: No plan yet. What are you working on?

Form label: Your plan (like a Unix .plan file)

Help text: Short note other users on this box can read. Examples: shipping macros, out until Thursday.

==========

5. PHASES ==========

Phase 1: deftype + plan/plan-of/plan-list + /plan + /u/:user Phase 2: /plans directory + home/chrome snippet Phase 3: optional public /u/:user; subdomain profile page

Success: alice sets plan macros + multi-user chat; bob opens /u/alice and knows what she's doing; chat stays for the actual conversation.

14 borge/auth.borg

pricklypear-auth

Pricklypear book chapter: auth
[status: partial]

– *agent note:* 2026-08-02 status reconcile: multi-user-product, user-subdomains, route-visibility ? implemented. Still partial: verification (argon2), user-ssh-repl (credential yes, full SSH door no).

auth

Multi-user identity: credentials, sessions, login, and binding each human to their garden
[status: partial]
Auth is in-process in the single image (image/lib/auth_password.ml, image/lib/auth_store.ml). It provides password verify, session mint/verify, SSH-key verify, and user CRUD; topology per single-image.borg.

credentials-store

The users, credentials, sessions, auth_log tables in Postgres
[status: implemented]
Tables (added by migrations, see migrations):
users (id uuid PK, username text UNIQUE, is_admin bool, user_type text NOT NULL DEFAULT 'human', – 'human' | 'agent' parent_user_id uuid NULL REFERENCES users(id), – agent's parent human; NULL for humans allow_agent_promote bool NOT NULL DEFAULT true, – human's toggle: may their agent promote – into their personal branch created_at timestamptz)
credentials (id uuid PK, user_id uuid FK, kind text, – 'ssh_key'|'password'|'web_token'|'api_key'|'llm_key' public_data jsonb, – SSH key material / llm last4+meta; – null for password (hash is secret) secret_data jsonb, – argon2 hash for password; – api_key token hash/reference; – llm_key provider secret (never list) created_at timestamptz, last_used_at timestamptz)
sessions (id uuid PK, – the token's opaque id user_id uuid FK, token_hash text, – SHA-256 of token; lookup target expires_at timestamptz, created_at timestamptz, revoked_at timestamptz NULL)
auth_log (id uuid PK, user_id text NULL, kind text, success bool, source_ip text, happened_at timestamptz)
KEY STORAGE (in-Postgres, role-isolated): - Other credentials (password hashes via argon2id, SSH public keys) in Postgres permanently; that's correct and stable (these are public verification material, not signing keys).

verification

verify(cred) / lookup / mint / verify_token – the four pure functions
[status: partial]
SSH KEY VERIFICATION: 1. Call verify_ssh_key(presented_key) -> May<user_id> 2. Auth: parse key, SELECT FROM credentials WHERE kind='ssh_key' AND public_data = key. Return user_id or denied. 3. Auth logs to auth_log.
PASSWORD VERIFICATION (for web login): 1. User POSTs username+password to /login. 2. Auth: SELECT secret_data FROM credentials WHERE kind='password' AND user_id= (SELECT id FROM users WHERE username=$1). Verify against the stored password hash. Champion is argon2id PHC-encoded; legacy sha256$salt$digest rows STILL verify and a successful legacy verify triggers a transparent in-place rewrite to argon2id (no flag day). Return user_id or denied. 3. Auth logs to auth_log.

TOKEN MINTING (after web login): 1. Auth: generate random token bytes (32B). 2. Auth: INSERT INTO auth_sessions (user_id, token_hash=sha256(token), expires_at=...). 3. Auth: return the raw token. Client stores it as the pp_session cookie (HttpOnly).

TOKEN VERIFICATION (on web requests): 1. Client sends token cookie. The image calls Auth_store.verify_token(token). 2. Auth: sha256 the raw token, look up the auth_sessions row by token_hash; check not revoked and not expired. Return user_id or denied. 3. Auth logs to auth_log.

API TOKEN VERIFICATION (for agents / pp_eval Bearer): 1. Client sends Authorization: Bearer <opaque_token>. 2. Auth: SHA-256 the token, SELECT FROM credentials WHERE kind='api_key' AND secret_data->>'token_hash' = $1. Return user_id or denied. 3. Auth logs to auth_log; updates last_used_at. 4. Tokens are per-user credential rows. No global tokens; every token belongs to a user_id. Generate/ rotate/revoke via /admin/users or a Nopales prim. The raw token is returned once at creation.

TOKEN FORMAT (minimal, NOT JWT): opaque_id (32B random) || HMAC(opaque_id) We control both ends; don't need JWT's cross-system interop claims. Hash stored in auth_sessions table enables revocation.

> – *agent note:* 2026-12: password champion is now argon2id with a transparent upgrade on successful legacy verify (auth_store.verify_password -> set_password). Legacy sha256$salt$digest rows still verify and are rewritten in place on first post-cutover login – no flag day, no dual-entry. BORGE-1785545259 closed (supersedes lost-id 1783831698 refs). Token/ssh_key paths unchanged.

bootstrap-admin

First-admin creation via env var on auth first boot

[status: implemented]

Bootstrapping the first user, with no users yet:

1. At auth boot, if the users table is empty, check env vars PP_BOOTSTRAP_USER and PP_BOOTSTRAP_PASSWORD (default: admin/admin). 2. If set, INSERT into users (username=$PP_BOOTSTRAP_USER, is_admin=true) and into credentials (kind='password', public_data=null, secret_data=argon2 hash of $PP_BOOTSTRAP_PASSWORD, user_id=the new user). 3. Auth boot: warn loudly in logs that bootstrap was used, and recommend clearing the env vars afterward. 4. After first boot, the env vars are ignored.

Subsequent users: added by an admin via the admin UI (which authenticates via auth) calling an auth primitive (create-user username, add-credential user_id ssh_key, etc.). These primitives require is_admin=true on the calling session.

No interactive bootstrap flow needed; the env-var pattern is simple, standard, and audit-logged.

audit-log

Every verification logged to auth_log

[status: implemented]

Every call to verify_ssh_key, password verification, mint, and verify_token writes a row to auth_log: (user_id NULL if unknown/failed, kind: 'ssh_key'|'password'|'mint'|'verify_token', success bool, source_ip text, happened_at timestamptz default now())

WHY from day one (despite personal-OS scope): - Cheap to add (one INSERT per verify call). - Invaluable when something goes wrong (compromised key? malicious insider? audit compliance if ever needed?). - Painful to retrofit (verification call sites scattered; adding log calls everywhere later means finding every one). - Standard practice; non-controversial.

The log is append-only in practice (no UPDATE/DELETE on auth_log). Retention policy deferred; for now, keep forever (cheap rows).

rpc-from-supervisor

Deprecated: auth is in-process; no RPC boundary
[status: deprecated]
Retired by the single-image pivot: auth is in-process. The supervisor no longer calls auth over RPC.

multi-user-product

COMPLETE multi-user product: many humans, each with identity, session, garden, authorship
[status: implemented]

> – *agent note:* 2026-08-02: users+sessions+personal branches+admin promote gate+logout revoke shipped (web-login/identity-and-branch/user-management). Cotenant isolation v1; per-user process fleet still future.
>
> *[verify] smoke: two users login independently; each sees own personal pins; smoke: Alice define does not create own pin on Bob's branch; smoke: non-admin cannot merge to system/main; smoke: agent install on Alice session writes alice/personal only; smoke: logout revokes session; next request requires login*

==========
MULTI-USER IS THE SYSTEM ==========
Pricklypear is a multi-user Lisp OS. Multiple humans share one deployment. Each human has: - a user row + credentials - a browser (and/or API) session - a personal branch garden: <username>/personal - authorship on their defines (function_defs.author) - isolation from other users' gardens and (when fleet is live) from other users' processes

single-image.borg simplifies HOW WE SHIP THE BINARY (one process to build/restart). It does NOT mean one human. multi-user.cotenant-isolation (one process, session + branch scoped) is the v1 isolation model; multi-user.isolation (per-user image process) remains a future hardening axis, not the shipping topology.

==========
PERSONAS ==========
Operator/admin – first user; can create users, merge to system/main, manage credentials, revoke sessions. Human user – logs in, works on <user>/personal, inherits system/main defaults, cannot admin-merge to system. Agent (as user) – authenticated as a human or service account; installs Nopales on that identity's branch; branch-locked for the task duration. Anonymous – only public routes (/login, health as policy).

==========
USER STORIES (complete set) ==========
US-BOOTSTRAP – First admin Empty users table ? bootstrap admin from env (PP_BOOTSTRAP_USER / PP_BOOTSTRAP_PASSWORD) OR one-time /setup form that creates admin then disables itself. is_admin=true. Site thereafter requires auth.

US-LOGIN – Browser sign-in GET /login ? username + password form. POST /login ? verify ? mint session ? Set-Cookie pp_session (HttpOnly; Secure; SameSite=Lax; Path=/). Redirect /. Bad credentials ? generic error + auth_log.

US-LAND – Land in my computer After login (or valid cookie): 1. Resolve user_id, username, is_admin from session. 2. Ensure branch <username>/personal exists as EMPTY child of system/main (inheritance, not full copy). 3. Image runtime identity = that user. 4. Checkout <username>/personal if not already. 5. (whoami) / chrome meta / define author = username. Alice never receives Bob's personal as current branch.

US-LOGOUT – Sign out POST /logout ? revoke auth_sessions row ? clear cookie ? /login.

US-SESSION – Stay signed in Every non-public request: load session by cookie ? valid unexpired unrevoked ? attach identity; else redirect /login (HTML) or 401 (API).

US-INVITE – Admin creates user Admin UI/API: create_user(username, is_admin?), set password credential, optional temp password. New user can US-LOGIN and gets own personal garden.

US-AGENT – Agent or laptop as a user Authenticate via same session cookie (cookie jar) OR API key credential (Authorization: Bearer ?) bound to a user_id. install_function / define write that user's current branch. Agent branch lock forbids checkout/ fork/merge mid-task. Author may be agent:<model> with provenance; capability still runs as the user.

US-SUBDOMAIN – Personal host name Each user has a stable URL on a wildcard base domain: https://{username}.{PP_BASE_DOMAIN}/ After login Alice lands on her subdomain (or is redirected there). Private work and public garden pages resolve against her branch chain. See auth.user-subdomains.

US-LLM-KEY – Bring your own model key Each user may store an LLM provider key (credentials kind llm_key). AI prims (propose-function, llm-*) use the session user's key; operator env LLM_API_KEY is fallback only. See auth.user-llm-keys.

US-SSH-REPL – Key-based shell into my image User registers an SSH public key (credentials kind ssh_key). Real SSH (or approved OpenBSD ForceCommand bridge) authenticates the key, attaches identity, opens the Nopales REPL on <user>/personal. See auth.user-ssh-repl.

US-CHAT – Talk to other humans on the box Authenticated users share a lobby and DMs (multi-user.chat). (chat/say ?) / /chat. Not email; same-deployment only.

US-PLAN – Unix .plan status Each user sets a short sticky plan (multi-user.user-plan). (plan "?") / /plan / /u/:user (finger). Complements chat.

US-COTENANT – Logical multi-user in one process (THE v1 model): One image process serves many sessions; identity is per-request; personal branch is per-session; no cross- user write to another's personal. Correct namespacing with a shared-process blast radius.

US-ISOLATION – Process isolation (future hardening axis) Logging in boots or attaches that user's image process (multi-user.isolation). Alice's wedge does not take Bob offline. Auth never sees fleet; fleet never sees raw passwords – only user_id from verify. Not the shipping topology in v1.

US-PERMS – Authorization - define/route/deftype ? current branch only - merge to system/* ? admin only - merge to own owner/* ? free for that owner - admin user CRUD ? admin session only - data_rows shared (existing rule) unless future row-level owner column is added

US-AUDIT – Failures are boring and logged auth_log for login success/fail, logout, admin acts. No username enumeration in errors.

==========

END-TO-END STORY ==========

1. Deploy; bootstrap admin. 2. Admin opens https://{PP_BASE_DOMAIN}/ ? /login ? signs in ? redirect https://admin.{PP_BASE_DOMAIN}/ on admin/personal. 3. Admin creates user "alice" + password. 4. Alice signs in ? https://alice.{PP_BASE_DOMAIN}/ on alice/personal (empty garden), inherits main. 5. Alice pastes her LLM key in /settings/keys; AI tools bill her provider, not the operator's env key. 6. Alice registers ~/.ssh/id_ed25519.pub; later 'ssh alice@host -p PP_SSH_PORT' opens her REPL. 7. Alice edits ui/menu ? pin on alice/personal only. 8. Bob signs in on bob.* ? bob/personal; no Alice pins. 9. Agent with Alice session/API key installs ? alice/personal. 10. Alice logout; cookie dead on her host. 11. With fleet (later): Alice's process is hers; Bob's is his. Cotenant single-image remains valid for v1 of subdomain

+ keys (identity per request / SSH session).

==========

OBJECTS (complete) ==========

users(id, username UNIQUE, is_admin, created_at) credentials(id, user_id, kind, public_data, secret_data, created_at, last_used_at) kind: password | api_key | ssh_key | llm_key | ? ssh_key.public_data: { "openssh": "ssh-ed25519 AAAA? comment" } llm_key.secret_data: { "api_key": "?" } (* never echo back *) llm_key.public_data: { "last4": "?", "base"?: url, "model"?: str } auth_sessions(id, user_id, token_hash, expires_at, created_at, revoked_at, user_agent, source_ip) auth_log(id, user_id NULL, kind, success, source_ip, happened_at)

Runtime image session (per connection / request): user_id, username, is_admin store.branch_id ? <username>/personal (default) author for define = username | agent:<model>

Password hashing: argon2id (implemented 2026-12: auth_password.ml champion matches Argon2 ID at t_cost=2, m_cost=65536, parallelism=1); interim sha256$salt$digest rows verify transparently and are rewritten to argon2id on successful login in-place.

Session token: opaque random id; store only HMAC/hash in DB; cookie carries raw id. Revocable. Expiry required.

==========

HTTP SURFACE (complete) ==========

Public: GET /login POST /login GET /health (policy: public or authed – choose public for ops probes)

Authenticated (any user): POST /logout all product routes (/, /todos, /notes, /api/eval, ?) identity-dependent branch + author

Admin: /admin/users (list, create, set password, revoke sessions) merge policy to system/* already enforced in Nopales prims

API: Cookie session OR Authorization: Bearer <api_key> same identity attachment as browser

nginx: TLS termination; reverse proxy to image(s). Complete system does NOT rely on htpasswd as the user database. htpasswd may exist only as emergency break-glass.

==========

FLEET ATTACH (future design sketch – per-user processes) ==========

v1 REALITY: identity attaches in-process at login; one image serves all sessions (see single-image.auth).

In a future per-user-process topology, on successful login / SSH verify an attach layer would resolve user_id ? boot-or-attach a per-user image with env: PP_USER_ID, PP_USERNAME, PP_BRANCH_ID, PP_BRANCH_NAME and proxy HTTP/REPL to that instance. Auth's component verifies + mints only; it never boots images.

==========

RELATION TO BRANCHES (already built) ==========

system/main – package defaults (seed from libs/*.pp) <user>/personal – empty-child garden; pins are "own" Effective Functions list = deduped closest-wins Agent locked to current branch during agent-task

Auth does not replace branching; it answers WHO is on which garden.

==========

NON-GOALS ==========

- OAuth / OIDC / social login - Email magic links (unless added later as a credential kind) - Sharing one password (htpasswd) among humans as the permanent multi-user model - Per-user process isolation as a blocker for subdomain/ llm_key/ssh_key (those ship on cotenant single-image first) - Custom domains per user (only {user}.{PP_BASE_DOMAIN} v1)

user-subdomains

Per-user Host: {username}.{PP_BASE_DOMAIN} as personal garden URL

[status: implemented]

– *agent note:* 2026-08-02: classify_host Host_garden + PP_BASE_DOMAIN in http_core; http.ml attach path uses host_mode; garden_url helper. Off when env unset.

[verify] build: dune build image; smoke: Host: alice.example ? garden context username=alice; smoke: logged-in alice on alice.example sees alice/personal; smoke: logged-in alice on bob.example cannot write bob garden; smoke: apex base domain serves welcome/login; post-login redirects to user host

Subdomain feature: when PP_BASE_DOMAIN is set, requests to {username}.{PP_BASE_DOMAIN} resolve to the user's personal branch garden (<username>/personal). The image parses the Host header, validates the username against the users table, and attaches that identity; otherwise, legacy single-host mode (path-only) applies.

user-llm-keys

Per-user LLM provider keys; session AI uses user key with env fallback
[status: implemented]

[verify] build: dune build image; smoke: user sets llm_key; propose-function uses it not empty env; smoke: user without key falls back to LLM_API_KEY env if set; smoke: GET settings never returns raw api_key; last4 only; smoke: Bob cannot read Alice llm_key credential

==========
1. WHY ==========
Today llm_client reads process env LLM_API_KEY only. Multi-user means Alice's AI spend and provider choice cannot be the operator's single key. Each human brings (or is issued) their own key; the image selects by session identity.
==========
2. CREDENTIAL SHAPE ==========
kind = 'llm_key'
secret_data jsonb (NEVER returned on list/get APIs): { "api_key": "<provider secret>" }
public_data jsonb (safe to show): { "last4": "ab12" // last 4 of key , "label": "synthetic" // optional , "base": "https://?" // optional override of LLM_API_BASE , "model": "hf:?" // optional override of LLM_MODEL }
Policy v1: at most ONE active llm_key per user (replace on set, like password). Multiple providers later via label/id.
Storage: Postgres credentials row; same role as other secrets. No encryption-at-rest beyond PG in v1 (same acceptance as password hashes / session signing risk profile – personal/small-team). Document footgun.
NOT the same as kind=api_key (that authenticates INTO pricklypear as Bearer). llm_key authenticates OUT to an LLM provider.
==========
3. RESOLUTION ORDER (llm_client) ==========
When a session invokes AI (propose-function, llm-inner, llm-outer, llm-rewrite, llm-seed, agent portal, ?):
1. If session has user_id AND credentials llm_key present ? use that api_key; apply public_data base/model overrides if set. 2. Else if env LLM_API_KEY non-empty ? operator fallback (dev). 3. Else ? clear error "no LLM key configured (add one in /settings/keys or set LLM_API_KEY)".
Threading: llm_client functions take optional ~auth_ctx / ~api_key / ~base / ~model rather than only reading env. Session layer fills from credential lookup (cached per request OK; invalidate on set/delete).

Anonymous / no session: AI prims denied (hard-private routes already); no env key leak via public pages.

==========

4. HTTP + LISP SURFACE ==========

Browser (authenticated user, self-service): GET /settings/keys form: status last4, set, clear POST /settings/keys body: api_key, optional base, model POST /settings/keys/clear

Admin may set/clear for another user via /admin/users (optional v1; self-service is enough for dogfood).

Nopales prims (session user only unless admin): (set-llm-key key [base] [model]) ? "ok" / last4 (clear-llm-key) ? VNil (llm-key-status) ? dict/list: configured?, last4, base?, model? NEVER returns raw secret.

auth_store: set_llm_key user_id ~key ?base ?model clear_llm_key user_id get_llm_key_meta user_id ? public_data option get_llm_key_secret user_id ? string option (* only called from server-side AI path *)

==========

5. SECURITY ==========

- Raw key only in POST body / Nopales arg / secret_data - Logs: never print full key (llm_client already prints model/url – keep it that way) - CSRF: same cookie session rules as other POSTs - User A cannot get_llm_key_secret for user B - Export/pp_sync: do NOT dump secret_data into lib.pp

==========

6. PHASES ==========

Phase 1: auth_store llm_key CRUD + llm_client ~api_key threading + session resolution + (llm-key-status) Phase 2: /settings/keys UI + set/clear prims Phase 3: optional per-user base/model; admin override UI

Success: two users, two keys, simultaneous propose- function calls hit distinct Authorization headers (observable via mock/test double or request log redacted).

user-ssh-repl

Per-user SSH public keys open an identity-bound Nopales REPL

[status: partial]

> – *agent note:* 2026-08-02 confirm partial: ssh_key credentials + verify_ssh_key + /settings/ssh UI shipped; full sshd/awa REPL attach still bridge/docs (docs/ssh-repl-bridge.md), not closed product door.
>
> *[verify] build: dune build image; smoke: add ssh_key credential for alice; verify_ssh_key resolves alice; smoke: SSH or bridge session attaches whoami=alice branch=alice/personal; smoke: unknown key denied + auth_log; smoke: password-only user without ssh_key cannot SSH*

==========

1. WHY ==========

Multi-user OS framing wants a real shell path: ssh alice@pricklypear.host -p $PP_SSH_PORT ? Nopales REPL as alice on alice/personal.

credentials.kind=ssh_key is already in the schema and historical supervisor/awa design. Single-image retired the supervisor fleet, so SSH must attach identity in-process (or via OpenBSD sshd ForceCommand bridge).

Browser login remains primary for v1 web; SSH is the power-user / agent-adjacent REPL door.

==========

2. CREDENTIAL SHAPE ==========

kind = 'ssh_key' public_data jsonb: { "openssh": "ssh-ed25519 AAAA?[comment]" , "fingerprint": "SHA256:?" // computed on insert , "label": "laptop" // optional } secret_data: null (public keys only; no private keys)

Multiple ssh_key rows per user allowed (laptop, desktop). Admin or self-service add/revoke.

auth_store: add_ssh_key user_id ~openssh_pubkey ?label ? parse type (ed25519 required v1; rsa deferred) ? store normalized openssh string + fingerprint list_ssh_keys user_id ? public metas revoke_ssh_key credential_id verify_ssh_key presented_openssh_or_blob ? user option (* compare fingerprint or canonical blob *)

auth_log kind='ssh_key' success true/false.

3. TRANSPORT OPTIONS (pick primary + ops escape)

Option A – awa-ssh IN THE IMAGE (product primary) - Image listens on PP_SSH_PORT when set (opt-in; unset = no SSH listener – same spirit as old PP_AWA_SSH_PORT). - Host key: seed in system_keys id 'image_ssh_hostkey_seed' (or reuse naming from historical supervisor_ssh_hostkey_seed). - Pubkey auth against credentials ssh_key for the claimed username (SSH user name = users.username). - On success: create/attach in-process session identity (user_id, username, branch personal), bridge channel to existing REPL endpoint semantics (line editor / eval loop). - CRITICAL: authenticated username MUST propagate into the REPL session (historical awa 0.3.1 gap where exec_callback lacked username – use awa version on poohstack that exposes auth identity, or map channel after auth event). No anonymous REPL.

Option B – OpenBSD sshd ForceCommand (ops escape) - System sshd on a dedicated port/user - authorized_keys generated/synced from credentials (periodic script or AuthorizedKeysCommand) - ForceCommand runs pp_repl_bridge that speaks to image REPL with fixed identity from key mapping - Document in openbsd-prod-branch-deploy.md - Acceptable if awa-in-image slips; product stories still require verify_ssh_key + key management UI.

v1 make should implement credential CRUD + verify + ONE working door (A preferred). B is documented backup.

Line-protocol pubkey pipe (nc + raw key) is DEV ONLY; not the multi-user product surface.

4. SESSION ATTACH AFTER SSH AUTH

Same as US-LAND / identity-and-branch: ensure <username>/personal checkout personal whoami = username author = username budgets from multi-user.budgets

REPL eval uses that session's env/prims – same as browser /api/eval for that user. No shared global env across SSH users on cotenant: each SSH connection has its own Session.t (or equivalent).

Disconnect: drop session memory; do not revoke browser cookies. Optional: no auth_sessions row for SSH (ephemeral connection identity) OR mint a short-lived session for audit – v1 ephemeral is fine; auth_log the login.

5. HTTP / UI

GET/POST /settings/ssh – list fingerprints, add pubkey, revoke. Self-service. Admin /admin/users – add/revoke ssh keys for a user.

Nopales: (add-ssh-key "ssh-ed25519 AAAA?") ? fingerprint (list-ssh-keys) ? list of {fingerprint,label} (revoke-ssh-key fingerprint-or-id)

6. RELATION TO DEPRECATED PATHS

image.ssh-interface and supervisor.* remain deprecated as multi-process topology. This subsection is the single-image successor: keys in auth credentials, listener in image (or sshd bridge), identity in-process.

Do not revive authd RPC for verify_ssh_key in v1; call auth_store directly inside the image.

7. PHASES

Phase 1: auth_store ssh_key add/list/revoke/verify + /settings/ssh + Nopales prims + auth_log Phase 2: awa-ssh (or sshd bridge) attach ? REPL with real whoami; PP_SSH_PORT opt-in Phase 3: harden hostkey rotation docs; agent use of SSH as alternative to HTTP Basic

Success narrative: Admin creates alice; alice pastes pubkey; alice runs ssh alice@host -p $PP_SSH_PORT; REPL prints whoami => alice; (define ?) pins alice/personal.

login-experience

What log in means: I present credentials and land in MY live image

[status: implemented]

> *[verify] smoke: human authenticates and lands on username/personal; smoke: unknown credential denied; no image attach for stranger; smoke: two concurrent users keep distinct identities*

Product bar (from multi-user-product): 1. Present credential (password browser, API key, or SSH key when SSH front door is live). 2. Verify ? user_id (never proceed on failure). 3. Mint or resume session; attach identity. 4. Ensure <username>/personal; set runtime branch. 5. With fleet: boot/attach that user's image. 6. User works; logout/revoke ends session.

Success: "I logged into my computer as me." Failure modes never leak other users' existence beyond generic invalid-credentials.

web-login

Browser password login, session cookie, middleware, logout

[status: verified]

> *[verify] build: dune build; smoke: POST /login valid -> Set-Cookie -> GET / as that user; smoke: POST /login invalid -> 401 + auth_log fail; smoke: POST /logout revokes; subsequent GET / redirects login; smoke: Alice and Bob cookies do not cross personal branches*

Complete browser path (part of multi-user-product):

GET /login Public form: username, password. No product chrome that assumes identity.

POST /login Body: username, password (+ CSRF token when forms are cookie-authenticated for other posts). verify_password against credentials.kind=password. On success: insert auth_sessions; Set-Cookie pp_session=<opaque>; redirect /. On failure: auth_log; same error for bad user/pass.

Middleware (request gate – see auth.route-visibility) Always ATTEMPT identity resolve (cookie then Basic). Classify path (system public / system private / user route visibility). Private + no identity ? login redirect (HTML) or 401 (API). Public may proceed anonymously. Identity present ? attach user even on public paths (optional auth).

POST /logout Revoke session; clear cookie; redirect /login.

Password: argon2id verify/hash in complete system. Cookie flags: HttpOnly; Secure; SameSite=Lax; Path=/.

nginx: TLS + reverse_proxy only for this path. htpasswd is not the user database.

HARD PUBLIC (kernel, not user-route table): /login /health /logout /welcome /book.pdf /src.tgz /code /code/* /assets /assets/* /.well-known/agent.json /agent.txt (public release face – product-experience.public-release; /book HTML explainer is private, not hard-public; /agent private portal stays hard-private) User-route public/private: auth.route-visibility.

route-visibility

Public vs private HTTP routes: store-backed visibility + OCaml request gate
[status: implemented]

– *agent note:* 2026-08-02: migration 006 visibility; public-route + route-visibility prims; live (route-visibility "/welcome") => public; /pages visibility column.

[verify] build: dune build image; smoke: migration 006 adds view_bindings.visibility default private; smoke: (route "/x" "h") stays private; unauth GET /x ? login redirect; smoke: (route "/pub" "h" 'public) ; unauth GET /pub ? 200 handler; smoke: logged-in GET /pub still attaches whoami (optional auth); smoke: unauth GET /data and /admin/users and /api/eval still denied; smoke: unauth GET /bindings /edit/foo /repl denied; smoke: /pages shows public/private badge per route; smoke: child branch inherits parent public route until override; smoke: re-(route path handler) without visibility keeps existing visibility OR defaults private – document choice; prefer KEEP on handler-only update

========== WHY ==========
The image already has a single request gate (launch in image/lib/http.ml): hard public allowlist, else require session/Basic. That is correct kernel shape – but it cannot express "this Nopales page is a public share link."

Product needs: - Default-private user routes (todos, notes, gardens) - Opt-in public user routes (marketing, shared deck view) - Kernel paths that are NEVER public via Nopales - Optional auth: public page still richer when logged in

NOT this subsection: - Per-row ACLs / Alice-vs-Bob data isolation (multi-user.permissions – later) - Capability bits on functions (separate) - OAuth / JWT (still out; wyo.auth / session cookie)

========== GATE ALGORITHM (authoritative) ==========
For every HTTP request to the image:

1. Parse path (strip query). 2. Resolve identity OPTIONALLY: cookie pp_session ? else HTTP Basic ? else None. Do not fail yet; just compute user_opt. 3. Classify path into one of:

A. SYSTEM_HARD_PUBLIC /login /health /logout /welcome /book.pdf /src.tgz /code and /code/* /assets and /assets/* /.well-known/agent.json /agent.txt (extend only by OCaml change; see product-experience.public-release; /book is NOT hard-public; /agent is NOT hard-public)

B. SYSTEM_HARD_PRIVATE Always require identity (Nopales cannot open these): /admin and /admin/* /data and /data/* /api/eval /api/agent /api/agent-task /api/ai/* /api/edit/* /api/recipe/* /bindings /binding/* /edit/* /repl /branches and /branches/* /types /pages /page/* /inspect/* /agent (Implementation: prefix/exact table in http.ml; when unsure, DEFAULT PRIVATE.)

C. USER_ROUTE Session.lookup_route path succeeds ? visibility from route record: "private" (default) | "public"

D. UNKNOWN No system page, no user route ? still require auth before 404 (do not leak route existence to anonymous via different status; v1 may 302 login then 404 after login – acceptable). Prefer: unauth ? login redirect for HTML; 401 for API Accept.

4. Decision: - If class A ? proceed (login form has no product chrome). - If class B or C-private or D: user_opt None ? deny (302 /login?next= or 401) user_opt Some ? attach_from_user ? proceed - If class C-public: user_opt Some ? attach_from_user ? proceed user_opt None ? proceed as ANONYMOUS (below)

5. PP_AUTH_DISABLED=1 ? proceed all (dev escape; unchanged).

No multi-layer middleware DSL. One gate function.

==========

ANONYMOUS SESSION (public + no identity) ==========

- (whoami) ? "anonymous" (string) or document VNil – pick one in make; prefer VStr "anonymous" for easy tests. - Branch: system/main (read package defaults). Do NOT create or checkout a personal garden for anonymous. - author for any accidental write: "anonymous" - WRITE POLICY v1: CRUD prims (create/update/delete) and define/route/fork/merge/checkout are DENIED for anonymous (raise clear error or return error VStr). Public pages are read-oriented. public-write (POST forms that mutate) is PHASE 2 – not v1. - Chrome: product ui/nav MAY render; avoid admin links. If ui/nav fails, emergency chrome only.

==========

SCHEMA (additive migration 006_route_visibility.sql) ==========

ALTER TABLE view_bindings ADD COLUMN IF NOT EXISTS visibility text NOT NULL DEFAULT 'private'; – allowed values: 'private' | 'public' – no CHECK required if app validates; optional CHECK OK

Fork copy of view_bindings MUST copy visibility (UPDATE fork INSERT column lists).

list_routes / register_route SELECT/INSERT visibility. Default private for all existing rows (DEFAULT).

scripts/dev.sh migration loop: add 006_route_visibility.

==========

LISP API ==========

(route path handler) ? register private route (default). If route already exists and only handler changes, KEEP prior visibility (so re-seed does not clobber an intentional public). If brand-new route ? private.

(route path handler 'public) (route path handler "public") ? register/update route with visibility=public. Third arg also accepts 'private / "private".

(public-route path handler) ? sugar for (route path handler 'public)

(route-visibility path) ? "public" | "private" | () () if no visible route on current branch chain.

Agent tools: register_route gains optional visibility field (default private).

==========

INHERITANCE ==========

Same recursive CTE as today: nearest branch wins for a path. Child can override parent public?private or private?public by re-routing on personal.

==========

UI ==========

/pages table: column Visibility (public|private). Optional: make-public / make-private forms later; v1 Nopales/REPL is enough.

==========

SECURITY NOTES ==========

- Public handler still runs full Nopales: author must not leak secrets in public pages. Document footgun. - System hard-private list is deny-by-default for kernel surfaces; never consult view_bindings to open /admin. - data_rows remain shared storage; public route ? row ACL. Sharing one deck is handler logic (filter by id), not "all flash-card rows are public." - /api/eval stays hard-private (agents use Basic auth).

==========

PHASES ==========

Phase 1 (this subsection make): migration 006, store/session route record, route prim arity, gate algorithm, anonymous read, /pages badge, smokes above. Phase 2: public POST / public-write visibility value; next= return path after login; CSRF for cookie posts. Phase 3: share tokens / signed URLs for single-resource public access without opening a whole route (flashcards).

==========

ACCEPTANCE NARRATIVE ==========

Dev marks (route "/hello" "hi-page" 'public). Logged-out browser opens /hello and sees the page. Same browser on /todos still hits login. /data still login. After login, /hello shows whoami in chrome. Re-seed of private routes does not wipe an intentional public flag when only the handler is updated.

user-management

Admin creates and manages users and credentials
[status: implemented]

> *[verify] smoke: admin creates user + password; new user logs in on own personal; smoke: non-admin cannot create users; smoke: admin can revoke all sessions for a user*

Complete admin surface: create_user(username, is_admin?, user_type?, parent_user_id?) set_password(user_id, password) add_credential(user_id, kind, ?) ; api_key, ssh_key list_users / get_user revoke_sessions(user_id) revoke_credential(id) create_agent(parent_username) ; user_type='agent', parent=human issue_token(user_id, label?) ; kind='api_key', returns raw token once rotate_token(credential_id) ; revoke old + issue new revoke_token(credential_id) ; delete credential row

First admin: bootstrap-admin (env) when users empty. All later humans: this API/UI only.

Agent users: user_type='agent', parent_user_id = the human they belong to. One agent account; model identity lives in the function_def author field, not the username. Agents auth via Bearer token (issue_token), not password. Agents inherit the parent's llm_key – get_llm_key_secret falls back to parent_user_id when the agent has no own llm_key row. Global tokens are disabled; all tokens are per-user rows in credentials.

UI: /admin/users (admin session required). Enforcement: is_admin on session; 403 otherwise.

Credentials order of support in complete system: password (web-login), api_key (agents/pp_eval Bearer – auth INTO the OS), ssh_key (SSH REPL door – auth.user-ssh-repl), llm_key (provider key OUT to LLM – auth.user-llm-keys).

Admin UI should grow links to manage ssh_key and llm_key per user; self-service /settings/* is the human path.

identity-and-branch

Session identity drives personal garden and authorship
[status: implemented]

> *[verify] smoke: whoami equals session username after login; smoke: define lands on username/personal; smoke: Functions origin own only for true personal pins*

On every authenticated request / image attach:

For human users: ensure_branch owner=username name=personal parent=system/main (EMPTY child; CTE inherit) store.branch_id = that id manifest.username = username manifest.branch_name = username/personal

For agent users (user_type='agent'): ensure_branch owner=parent_username name=agent parent=system/main (EMPTY child; sibling of the parent's personal). The agent's default workshop is <parent>/agent, NOT the parent's personal. store.branch_id = that id manifest.username = agent identity (whoami returns the agent, not the parent) manifest.branch_name = parent/agent

(define name body) persists with author=username (or agent:<model> when agent installs under policy).

Agent llm_key: get_llm_key_secret falls back to the parent human's key when the agent has no own llm_key row.

Functions UI: effective one-name-one-row; origin own vs inherited (already implemented).

Agent-task: agent_branch_lock blocks checkout/fork/merge (already implemented); must run under the user's session.

Changing user mid-process (cotenant): rebind identity + checkout personal for that user; never leave previous user's pins writable.

15 borge/image.borg

pricklypear-image

Pricklypear book chapter: image
[status: partial]

> – *agent note:* 2026-08-02 status reconcile: flipped htmx/http-robustness/system-browser/tree-browser/function-editor/inspector/dnu-stubs ? implemented. Still partial: repl-experience (linenoise), per-request-context (store phase).

image

The per-user unikernel: Nopales interpreter, REPL endpoint, htmx interface
[status: partial]

boot

Single-image boot process: initialize Postgres, load stdlib, start services
[status: verified]

> *[verify] build: dune build image; smoke: image boots + serves / and /health + REPL accepts connections*

On boot, the image: 1. Reads identity from process environment: PP_USERNAME (REPL prompt), PP_BRANCH_NAME, PP_BRANCH_ID. 2. Connects to Postgres via pgx_lwt. 3. Applies pending migrations (additive-only). 4. Runs seed_stdlib: loads libs/*.pp into system/main. 5. Starts the REPL endpoint (internal line protocol on PP_REPL_PORT if set). 6. Starts the htmx server (httpaf-lwt-unix) on PP_HTTP_PORT. 7. Registers health endpoint at /health.

The image is STATELESS across reboots w.r.t. user data: anything that must survive is in Postgres. In-memory REPL state (define'd locals in a session) does NOT survive reboot unless the user persisted via (store) or similar.

boot-seed-batch

Boot seed batch-loads existing names once; additive persist skips per-name SELECT
[status: implemented]

> *[verify] build: dune build image; smoke: warm boot: image.log shows one [session] boot seed: N packages, M defs in <ms>ms line and ZERO get_by_path-per-define round trips; first POST /api/eval after boot < 2s; smoke: cold boot (fresh DB): every seeded name is present in (list-bindings); package provenance stamped*

Boot seed is ADDITIVE (branching.seed-policy option A): existing system/main rows are never clobbered. The expensive part of seed_stdlib is NOT rehydrate (it suppresses refresh and rehydrates once via checkout_personal at boot end) – it is that persist_function_if_absent / register_route_if_absent each performed a Tree_store.get_by_path SELECT per name. With ~1800 defines + ~34 routes that was ~1800 PG round trips on EVERY boot, warm or cold.

BATCHED SEED: seed_stdlib preloads the set of existing function names AND route paths on system/main ONCE (two queries) into a per-store seed-membership cache. persist_function_if_absent and register_route_if_absent consult that cache instead of issuing get_by_path per call: - name in cache -> skip entirely (no SELECT, no UPDATE, no upsert). Additive seed never touches existing rows. - name absent -> upsert into the store AND insert into

the cache, so later duplicate defines in the same seed pass are skipped too. The cache is populated only for the seed_additive boot pass on system/main; interactive load_library and reseed-package keep their existing per-call semantics.

INVARIANT: additive seed never overwrites an existing body. Skipping the existing-name path therefore preserves seed-policy exactly.

INVARIANT: boot logs one summary line [session] boot seed: <n> packages, <m> defs in <ms>ms so first-eval latency regressions are visible in /tmp/pp-dev/image.log.

boot-request-cost

/api/* never triggers the UI shell; identity attach never rehydrates an unchanged branch

[status: implemented]

> *[verify] build: dune build image; smoke: POST /api/eval with a cold ui-shell cache does NOT evaluate ui/nav or ui/css; GET / does; smoke: two identical Basic-auth POST /api/eval calls in a row trigger zero rehydrate*

Two per-request costs are removed or confirmed cheap for the agent path.

refresh_ui_shell INVARIANT: the UI shell (ui/nav, ui/css) exists for HTML chrome. The request gate calls refresh_ui_shell ONLY for paths that render chrome. /api/* handlers NEVER trigger a ui/nav or ui/css eval, even when the shell cache is cold. (The 60s TTL cache already amortizes HTML-page requests; this removes the cold-first-eval cost from the agent path entirely.)

attach_identity INVARIANT (already holds, documented): if the resolved identity's username equals the session's current manifest username, attach is a manifest-field update only – it MUST NOT call ensure_personal_branch / checkout_personal / rehydrate. Rehydrate happens only when the branch actually changes (prev <> username or explicit checkout). Repeated Basic-auth requests from the same user therefore never rehydrate.

lazy-env-load

load_defs binds VThunk recipes instead of evaluating bodies; rehydrate is one CTE + decode, never a body eval

[status: implemented]

> *[verify] build: dune build image; smoke: rehydrate of the full branch chain completes in ms; zero [session] load def lines logged; smoke: a def whose body executes only runs (and logs failure) on FIRST reference, not at checkout/attach*

The image half of lisp-interpreter.lazy-env-thunks.

load_defs walks the recursive-CTE def list (parents first, child overrides) and binds each name to a VThunk payload whose force evaluator is the SESSION's rim eval (Control_rim.run around Eval.eval with the current budget when one is active, fresh budget otherwise). Macro bodies keep the old eager path (VMacro construction is pure, no eval). Defs whose stored body is an APPLICATION form – data captured as code (rb/* recipes, outline experiments, seeds) – no longer execute at boot/checkout/attach; they cook once on first reference, under the forcing request's budget, and memoize (value OR failure).

SEMANTIC CHANGE (deliberate): nothing at image scope may rely on load-time side effects of stored def bodies. A def is a recipe, not an init hook. If boot order matters for a real side effect, it belongs in boot code, not in function_defs. Alphabetical-load-order breakage of the old scheme (rb/* evaluated before recipe was defined ? 28 defs failing on EVERY rebuild, re-running partial side effects each flip) disappears: forcing resolves through the fully linked env.

per-identity-sessions

One Session.t per attached identity (env+routes+store handle); attach selects, never mutates; anonymous gets its own parked session

[status: implemented]

> *[verify] build: dune build image; smoke: alternating anonymous GET /welcome and Basic-auth POST /api/eval: neither pays a rehydrate when nothing changed; smoke: a define by admin is visible to the anonymous session within one staleness check; smoke: concurrent requests for two users run page work in parallel (no head-of-line blocking)*

PROBLEM (measured on prod 2026-08-21) One shared Session.t + per-request attach meant every alternating-user request flipped the session's branch and paid a FULL rehydrate under the global request_mutex (60-120s on admin/personal with ~4000 defs ? strict eval). boot-request-cost's invariant ('rehydrate only when the branch actually changes') was vacuous: with one session, every OTHER user's request IS a branch change. The cotenant race that Request_context snapshots band-aid exists only because the session is shared.

MODEL Session_registry owns a Hashtbl identity -> Session.t: - one long-lived anonymous session, parked on system/main, serves all unauthenticated traffic (public face: /welcome, /agent.txt, public routes) - one session per authenticated username, built lazily on first attach, parked on that identity's branch - each session has its OWN Store.t (own pgx connection): checkout mutates only its own store, and the global pgx sequencer serialization between users disappears - attach = resolve identity -> select (or create) -> cheap staleness check -> serve. Attach NEVER checks out another identity's branch.

STALENESS A parked session must notice writes on its visible chain (another user's promote, an agent's define). At attach, one cheap query per session – count(*)+max(updated_at) over function_defs / view_bindings / type_defs on the session's branch chain – compared against the values at last load; mismatch triggers rehydrate (cheap under lazy-env-load). Attach cost when idle: one indexed round trip, ~ms.

CONSEQUENCES - Invariant 4's cotenant race is deleted at the root: Request_context remains as the per-request snapshot discipline, but no concurrent attach can mutate the session a page is reading, because page work runs on the identity's own session. - request_mutex narrows to registry table access; page work across identities parallelizes (subject to PG). - Sessions are never expired in v1 (user count is small; revisit with an LRU if a public signup flow appears). - Boot session remains for boot/seed/jobs-runner use.

function-stat-ring

function_stat writes go through an in-process ring flushed by a background fiber; no per-eval DB write

[status: implemented]

> *[verify] build: dune build image; smoke: burst of labeled evals produces zero synchronous data_rows writes; flush fiber lands them <= 30s later*

Every labeled /api/eval called Crud.create for a function_stat row – a synchronous SERIALIZABLE insert + fsync on the request path, and 54k unbounded rows on prod after a few weeks. Same medicine as http-robustness's ops-incidents rule: request path pushes to an in-process ring (capacity 512, drop-oldest), a background fiber flushes at most once every 30s. Loss on crash is acceptable: these are perf stats, not ledger.

ssh-interface

Deprecated: SSH access removed in single-image pivot

[status: deprecated]

[verify] build: dune build @all; smoke: SSH access removed – use browser /repl or POST /api/eval

The single-image pivot removed supervisor and SSH. Interactive access is via: - Browser REPL at /repl - Agent API at POST /api/eval - Optional line-protocol REPL on PP_REPL_PORT (if set)

repl-endpoint

Image's internal REPL endpoint, not full SSH
[status: implemented]

[verify] build: dune build image; smoke: define over the line REPL persists to the store; a second session sees it

The image does NOT run an SSH server. It optionally exposes a line-protocol REPL – a simple TCP socket on PP_REPL_PORT (unset = no listener), intended as an operator surface on a trusted network. The primary interactive surfaces are the browser /repl and POST /api/eval (both authenticated).

Protocol (minimal, framed): - Connect: operator opens TCP to image:PP_REPL_PORT - Auth: none on the socket itself – the port is bound for operators only; do not expose it beyond the trusted network - Exchange: lines of UTF-8. User input flows in; REPL output flows out. - The image's session.ml tracks this connection as a session; on disconnect, session ends.

The endpoint is in image/lib/repl_endpoint.ml. It owns: accepting connections, wiring the stream to the line editor (lineedit.ml), and the REPL read-eval-print loop itself.

repl-experience

What the user sees: prompt, multi-line, line editing, meta-commands
[status: partial]

– *agent note:* 2026-08-02 confirm partial: lineedit.ml is minimal read_line stub; linenoise history/cursor still TODO. browser-repl covers interactive UX.

[verify] build: dune build image; smoke: define + apply works end to end through the REPL

THE PROMPT: alice/main> – showing user + current branch alice/main (def) | – mid-multiline-define

READING INPUT: - The REPL reads s-expressions. It keeps reading lines until parens are balanced and strings closed (standard Nopales REPL behavior). The reader tells us 'incomplete' so we know to prompt for more, not to evaluate yet. - One REPL turn = one s-expression (which may span many lines). - Comments: ; to end of line, as in the reader.

LINE EDITING: - Real line editing matters for a dev tool. Raw SSH PTY + a line-editing layer. - Library choice deferred to build time: ocaml-linenoise is the leading candidate (small, Mirage-compatible-ish). Pure OCaml. - Supports: cursor movement, history (up/down), Ctrl-A/E, backspace, delete. - Search/history-reverse-search: nice-to-have, not v1-blocking.

EVALUATION + PRINTING: - Evaluate the s-expression in the session env. - On success: pretty-print the resulting value. VList -> (a b c), VLambda -> #<lambda>, VRef -> #<ref event:uuid>, VInt -> 42, etc. - On error: print the error with location if possible (line/col from the reader), then a continuation prompt. Don't kill the session.

META-COMMANDS (Nopales forms, not a separate command lexer – the reader handles them, the eval loop recognizes them as special forms): (define name expr) bind + persist to store (edit name) print htmx URL for AST editor

(fork parent child) create a branch (checkout branch) switch session's branch (merge source target) reviewer flow (describe 'type) show type schema (list-bindings) current env (load "file") eval a file's contents (help) list specials Any other Nopales form evaluate + print result

SESSION STATE: - (define ...) persists to the store: survives image reboot (loaded on next boot of the branch). - REPL-local let bindings (e.g. (let ((x 5)) ...) at top level): session-local, not persisted. Like bash variables. - Switching branch (checkout) within a session keeps REPL locals but changes which function defs are visible. (Decision: this is the 'working directory' model – you carry your locals across branch switches.)

htmx-interface

User routes accept GET and POST; request context available via dynamic-binding prims. bible/* and other handler-only fns now guarded (require_request raises Interp_error User_error on direct /api/eval; api_eval catches as clean JSON error – fixes inbox c5-1054).

[status: implemented]

> – *agent note:* 2026-08-02: request-method/param/params + redirect prims; user routes GET/POST via http.ml; auth/lib/http.ml path retired (in-process).
>
> *[verify] build: dune build image; smoke: POST user route hits same path handler; (request-method) => POST; smoke: POST form-urlencoded body: (request-param "title") returns field; smoke: GET query: (request-param "q") returns query value; smoke: (redirect "/todos") => 303 Location: /todos; smoke: POST /api/recipe/todo then POST /todos title=? creates row + redirects; GET /todos lists it*

The image's htmx endpoint serves two kinds of pages:

1. SYSTEM pages (always present, part of the OCaml image): /health health check /inspect/binding/<name> pretty-print one function_def's AST /inspect/row/<type>/<id> browse any stored value /branches list + fork/merge UI /types type browser (type_defs) /data ? data rows browser (full CRUD; see image.data-browser) /bindings function browser (per branch)

2. USER pages (defined as functions in the store): registered via (route "/path" fn-name). The route handler runs with a REQUEST CONTEXT (method, path, params) and returns a value the system renders (HTML, redirect, text, etc).

Routes ARE functions in the store. Adding a route = (route "/foo" 'foo-handler). This makes the user-facing UI part of the live image, editable via the same mechanisms as everything else.

ROUTE VISIBILITY: User routes default private (session required). (route path handler 'public) opts into anonymous GET. Kernel paths (/data /admin /api/eval /bindings /edit ?) are hard-private in OCaml and cannot be opened by Nopales. Gate runs before handler dispatch.

pure-html (the dream_html HTML generation core, usable WITHOUT Dream) is used for HTML generation (use Hx.* not raw strings at the OCaml layer).

REQUEST CONTEXT (dynamic, handler-scoped): Zero-arg handlers keep working: (define hi-page (lambda () (render-html "?"))) Interactive handlers read request via prims while the HTTP dispatch is inside call_handler: (request-method) -> VStr \"GET\" | \"POST\" (request-path) -> VStr path without query (request-param k) -> VStr value | VNil if missing (request-params) -> VStr JSON object of all params (request-body) -> VStr raw body (\"\" on GET)

HANDLER RETURN VALUES: 1. render-html tagged VStr (___html___:?) -> 200 text/html, body = raw HTML inside chrome 2. bare VStr -> 200 text/html, <p> escaped text 3. other values -> 200 text/html, <pre> pp_value

4. (redirect path) -> tagged VStr ___redirect___:path -> HTTP 303 See Other, Location: path, empty/minimal body Path must be absolute-on-host.

http-robustness

HTTP server robustness under load, peer disconnect, and DB liveness
[status: implemented]

> – *agent note:* 2026-08-02: closed-writer swallow, request_mutex narrowed to gate, page-work queue, Store.health_check on /health, http_robust tests present.
>
> *[verify] build: dune build image; smoke: abort N concurrent requests mid-response; image stays up, /health 200 throughout; smoke: open SSE /api/agent stream, disconnect client; no Fatal error in image.log, process pid unchanged; smoke: fire M concurrent mixed routes (page + SSE + /api/eval); all complete or peer-gone, zero process exits; smoke: GET /health returns ok:true only when SELECT 1 on store succeeds; ok:false + non-2xx when DB path is dead; smoke: rcctl check fails when /health reports ok:false; watchdog restarts a live-but-poisoned image; test: image/test/http_robust_test.ml – closed-writer guard returns () not raises; catch-body does not re-write to dead writer; test: image/test/io_eio_test.ml – Sequencer.enqueue survives a raised SQL-like exception and subsequent enqueue still runs*

The httpaf body writer raises Failure("cannot write to closed writer") when you write to a response whose client has disconnected. On a single-image process, one uncaught closed-writer exception is a process exit. These invariants make a peer-disconnect a non-event, and define the concurrency model so the server does not serialize all traffic behind one lock.

==========
INVARIANT 1 – PEER-DISCONNECT IS NEVER FATAL ==========
Every code path that writes an HTTP response body MUST tolerate a closed/gone writer by returning () (or a benign 'Peer_gone signal), never by raising. A client closing its tab is the single most common event on a web server; it must not take the process down.

Mechanism (http_core.ml):

- is_closed_writer_exn : exn -> bool - safe_respond_with_string : respond_with_string wrapped; swallows the closed-writer Failure - safe_close_writer : close_writer wrapped; swallows the closed-writer Failure

EVERY response helper routes through the guarded path: html_response, text_response, json_response, fragment_response, redirect_response.

The httpaf error_handler (http.ml error_handler) writes unguarded via Body.write_string + close_writer; it MUST be guarded the same way – it runs on connection-level errors where the peer is very often already gone.

==========
INVARIANT 2 – ERROR RECOVERY MUST NOT RE-WRITE A DEAD WRITER ==========
launch's Lwt.catch exception branch (http.ml) currently responds to a handler failure by calling html_response ... ~status:'Internal_server_error on the same reqd. If the original failure was a closed-writer (peer gone), the recovery write fails the same way and escapes the catch.

Rule: the catch branch MUST detect the closed-writer case (is_closed_writer_exn on the caught exn) and, instead of rendering a 500 page, just safe_close_writer the (already-dead) writer and return. Only when the writer is still alive do we render the 500 error page.

Concretely: in the (fun exn -> ...) handler, branch: if is_closed_writer_exn exn -> safe_close_writer; Lwt.return_unit else -> Ops_incidents emit + html_response 500 This breaks the throw-in-the-catch loop that would otherwise turn one peer-disconnect into a process exit.

==========
INVARIANT 3 – ui/nav FAILURE IS NOT PER-REQUEST NOISE ==========
refresh_ui_shell runs on every request (http.ml launch). When ui/nav is broken on the branch it logs a [warn] line PER REQUEST – under HN traffic this produced hundreds of warn lines and wasted a Nopales eval per page.

Rule: refresh_ui_shell MUST cache its failure state per branch (at least short-TTL in-memory): once ui/nav has failed on a branch, do not re-attempt and re-warn on every request; downgrade to a single debug line (or a periodic retry on the order of minutes, not per-request). The emergency chrome fallback already serves the page; the spam is pure waste. This is not a crash fix but a log-hygiene + cost fix surfaced by the same incident.

==========
INVARIANT 3.5 – INCIDENT AUTO-FILING IS ASYNC, NOT IN THE REQUEST FIBER (2026-08 incident-write amplification) ==========
A repeating route failure (e.g. ui/home unbound on a branch) used to call Ops_incidents.emit_and_maybe_file on EVERY page hit: a synchronous Crud.create (+ tree-mirror trigger writes + a TODO row) inside the request fiber, multiple serialized PG round-trips per request – observed as GET / taking 10-40s with DB writes mid-request.

Rule: Ops_incidents buffers events in an in-process ring (dedup by fingerprint, count++ coalescing as today); a background fiber flushes the ring at most once every N seconds. Request-path cost of auto-filing is a ring push ONLY – zero DB ops. One repeating bug = one incident row + one TODO total, not one per page view.

==========
INVARIANT 4 – CONCURRENCY: IDENTITY ATTACH IS SERIALIZED, PAGE WORK IS NOT (immutable-env + narrowed mutex) ==========
Status quo: a single global request_mutex (http_core.ml) is held for the ENTIRE request lifecycle – identity resolve, classify, refresh_ui_shell, AND page_fn (including slow LLM/SSE streaming). This serializes the whole site to one-request-at-a-time and, worse, lets one streaming agent chat block /login and / for everyone.

The naive fix (just release the mutex before page_fn) is UNSAFE because Session.t is one shared mutable record and page work reads two shared mutable fields: (1) t.env – rehydrate does Hashtbl.clear t.env.bindings IN PLACE. VLambda closures capture env by reference (env = { bindings: Hashtbl.t; parent }), so a concurrent rehydrate during page eval would empty the binding table an in-flight lambda is reading through its captured env -> unbound-var mid-page. (2) t.manifest – attach_identity mutates t.manifest in place; prims (crud, agent) read t.manifest.username live via the !t ref they close over. A concurrent other-user attach would flip the username mid-page -> wrong-user attribution for writes.

RULE (two parts):

4a. IMMUTABLE-ENV REHYDRATE (the correctness prerequisite). rehydrate MUST NOT mutate the existing env's binding table in place. Instead it builds a FRESH env record (new Hashtbl, same parent chain) and swaps Session.t.env to point at it. Session.t.env becomes a mutable field. The OLD env record stays intact for the lifetime of any VLambda closure that captured it, so a concurrent rehydrate cannot corrupt an in-flight page's captured environment. This is the foundation that makes any mutex-narrowing safe.

4b. NARROWED MUTEX. request_mutex protects ONLY the identity-attach critical section (resolve_identity + attach_from_user / attach_anonymous + classify + the post-attach refresh_ui_shell). The mutex is released BEFORE page_fn runs. Page work – user-route handlers, /api/eval, and the agent SSE streaming loop – runs WITHOUT the global lock, against the (now-immutable) env captured by closures.

4c. PER-REQUEST CONTEXT (fix for BORGE-1784434193 cotenant race). After the identity gate, a fresh Request_context.t is built from the

attached manifest/env/routes and passed to all page work. Prims and dispatch read the context instead of live Session.t fields. Anonymous attach can no longer flip an in-flight personal-branch page.

SUPERSEDED ROOT CAUSE (image.per-identity-sessions): the cotenant race existed because ONE Session.t was shared across identities. With per-identity sessions, attach no longer mutates a session another request is reading; Request_context stays as the snapshot discipline, but 4a's fresh-env-swap requirement ceases to be load-bearing for cross-user safety (still useful for same-session rehydrate during long page work).

(subsection per-request-context (doc "Request_context.t + dynamic binding to eliminate cotenant race") (status partial) (* agent note (|2026-08-02 confirm partial: Request_context.t snapshots manifest+env+copied routes; prims use dynamic binding. Remaining: store on context (phase 3) + full prim audit.|) *) (implements image/lib/request_context.ml image/lib/http.ml image/lib/session.ml image/lib/primitives.ml image/lib/crud.ml) (verify (build "dune build image") (smoke "admin/personal route survives concurrent anonymous attach") (test "image/test/http_robust_env_test.ml extended for manifest isolation")) (details (doc (| Shipped mechanism (direct-style, post-H1): - Request_context.t record (manifest snapshot, env, routes, store, request) in image/lib/request_context.ml. - Request_context.current is a dynamically-bound per-request snapshot; prims read the snapshot, not the live shared Session.t ref. with-public-write re-binds an elevated context for the body so static gate and runtime guard agree. - Route dispatch reads context.routes; page work after the attach gate runs against the snapshot, so a concurrent anonymous attach cannot swap the manifest mid-render. - Session.t still used for attach gate + rehydrate/checkout_to. - The earlier plan to change the prim ABI to Request_context.t -> value list -> value Lwt.t is retired: H1 made the prim ABI direct-style (prim_fn = value list -> value, Control.perform_prim) and the context travels by dynamic binding instead of an explicit first argument. - Remaining: full env/routes snapshot isolation depth and the audit that every prim reads the snapshot (phase 2). |)))

SCOPE / MULTI-TENANT CAVEAT (honest): the manifest race (4b concern 2) is NOT fully closed by this work. Prims still read t.manifest live via the !t ref. This is safe ONLY while concurrent requests share one identity (one authed user, plus anonymous traffic sharing manifest.username=anonymous): t.manifest reads during page work then cannot attribute a write to the wrong user. Cotenant operation with DISTINCT authed users concurrent needs a per-request manifest context threaded through the prim dispatch so prims read the request's manifest, not the shared record. That is deferred to a follow-up borge issue (ABI surgery on prim_fn; not a crash/throughput fix). Until it lands, cotenant hosting of multiple simultaneously-active users carries this documented caveat.

The single shared Postgres connection (Store.t.conn) remains a throughput ceiling, NOT a correctness risk under the narrowed mutex: pgx_lwt serializes all operations on a connection internally via its per-connection Sequencer (type t = conn Sequencer.t; every execute/with_transaction goes through Sequencer.enqueue = Lwt_mutex.with_lock on a per-connection mutex). Concurrent Pg.execute calls on the same conn therefore QUEUE safely – no wire interleave, no corruption. So narrowing request_mutex does NOT require a separate db_mutex: DB prims stay correct (serialized by pgx) and page rendering (Nopales eval, HTML build – the slow part) runs lock-free. The single conn is still a throughput ceiling (a pool is a separate later iteration), but it cannot corrupt under concurrency.

==========

INVARIANT 5 – ACCEPT-SIDE CONNECTION CAP ==========

Status quo: serve (http.ml) calls Httpaf_lwt_unix.Server.create_connection_handler with no limit and Lwt_io.establish_server_with_client_socket with no backlog/fd cap. Under a spike the accept loop can exhaust fds or memory even

after crashes are fixed.

Rule: gate the acceptor on a bounded semaphore (an Lwt_semaphore or a counter with a max, default 256 in-flight requests, configurable via PP_HTTP_MAX_INFLIGHT). Requests beyond the cap are rejected early with a 503 (or simply not accepted until a slot frees). This bounds fd/memory usage to a known ceiling regardless of traffic. The cap is a safety valve, not a throughput target – normal load should be well under it.

NOTE: this is defense-in-depth on top of the crash fix. The crash fix (invariants 1-3) is what stops the death loop; the cap (invariant 5) plus the mutex narrowing (invariant 4) are what make the server survive the next traffic spike on throughput, not just on not-crashing.

==
INVARIANT 6 – EIO PG SEQUENCER MUST NOT PERMANENTLY POISON ==
Incident 2026-07-22 (pricklypear.rocks): under PP_IO=eio the live image kept serving /health 200 while every auth/DB call failed with Eio___Eio_mutex.Poisoned(_). Login and Basic auth both surfaced as "Invalid username or password" because auth_store.password_hash_for_user catches all exceptions and returns None. The process stayed up for days; the watchdog never fired because /health never touched the DB.

Root cause: Io_eio.Pgx_io.Sequencer.enqueue used Eio.Mutex.use_rw ~protect:true. Eio documents that use_rw DISABLES the mutex forever if fn raises – any SQL error (or cancel) permanently kills the single shared PG conn sequencer. Subsequent enqueues raise Poisoned.

Rule: the pgx Sequencer critical section MUST unlock on exception (use_ro-style unlock-and-re-raise), while still using Cancel.protect so cancellation cannot leave the wire mid-message. Do NOT call use_rw for the sequencer: a raised Pgx/PostgreSQL error does not mean the mutex resource invariant is broken – the connection protocol recovers; only the operation failed. Optional later: detect hard I/O death and reconnect Store.t.conn; that is separate from not poisoning the lock.

Mechanism (io_eio.ml Sequencer.enqueue):

lock; Cancel.protect (fun () -> f v); unlock on exception: unlock; re-raise

Never poison. Never leave the mutex locked.

==
INVARIANT 7 – /health PROBES DB LIVENESS ==
/health remains hard-public and outside the inflight page cap (invariant 5 note). But "ok" MUST mean the image can still talk to Postgres on the store path used by auth and prims – not merely "process is alive and JSON encodes".

Rule: - GET /health runs SELECT 1 (or Store.health_check) on Session.store via the same dual-conn exec path. - On success: HTTP 200, {"ok": true, ... error: null}. - On failure (no conn, query error, Poisoned residual, timeout): HTTP 503, {"ok": false, error: "..."}. - Cheap: one round-trip; must not take request_mutex or the inflight page semaphore. - rc.d rc_check and the promote health loop MUST match ok:true (not merely the substring "ok" – "ok": false must fail the check). - Watchdog: when rcctl check fails, stop/kill stale image (pidfile + pkill -U runtime user on bin/image) then start. Plain rcctl start is insufficient when a live-but-poisoned process still holds :18080 without a usable pidfile (EADDRINUSE on start). - rc_stop / promote restart path: always clear the port before start (pkill runtime image; rm stale pidfile).

This closes the class of failures where the accept loop is healthy but the DB mutex/conn is dead – the failure mode that locked out all logins while looking green.

primitives-layer

image/lib/primitives.ml: the impure fns registered at boot

[status: implemented]

> *[verify] build: dune build image && cd lisp && dune build && dune runtest; test: image/test/primitives_test.ml 48 alcotest cases; lisp/test/eval_test.ml 30 pure tests*

See lisp-interpreter.primitives for the full primitive list. This subsection covers the IMAGE layer's responsibility: registering them with the interpreter at boot.

The interpreter is pure and knows nothing about Postgres, htmx, or SSH. The IMAGE layer: 1. Opens a Postgres connection (v1: pgx_lwt + custom Io_unix shim; Solo5 later may use pgx_lwt_mirage behind the same Store.t). 2. Constructs an initial env with VPrim values bound to names like 'get', 'create', etc. 3. The interpreter's Prim call dispatches by name to the OCaml function the image registered. 4. Each primitive handles its own transaction (SERIALIZABLE by default) and permission checks (per multi-user.permissions; author- scoped filtering still partial).

This separation is what makes the interpreter testable without any services running (pure lisp/test/eval_test.ml, no DB, no HTTP).

v1 SHIPPED registration path: real. Kernel I/O prims shipped (Effect.pure_prims / Net): http-get (Net; admin/agent), xml-parse, html-decode, parse-date, url-encode/decode, sha1, string helpers, random-uuid, now, now-ms, sleep (Lwt, max 60s/call). DEFERRED: Solo5 pgx path; host cron/scheduler table.

define-docstring (lisp-interpreter): image registers (function-doc name) and wires Store.persist_function ?doc so top-level define can document bindings into function_defs.doc. See that subsection for surface syntax and redefine/clear rules.

outbound-http

(http-post url headers-json body) – send-side sibling of the shipped http-get. Same curl-backed shape, same gate, same payload contract. The first consumer is notify.ntfy-delivery (lock-screen push from jobs schedules).

[status: planned]

> – *agent note:* 2026-12 plan pass: daily-scripture campaign. The Net effect tag already exists in the lattice (lisp/lib/effect.ml tag 8; net_prims = [http-get]); http-get is shipped (prims_net.ml, curl-backed, admin/agent-only). http-post is the additive send half.

> *[verify] build: dune build image; smoke: (http-post "http://127.0.0.1:18080/health" "{}" "x") as admin returns a payload dict with ok/status/body; smoke: anonymous + non-admin/non-agent caller -> denied Prim_error, same gate as http-get; smoke: unreachable host raises transient Prim_error (curl (7) ...), NOT a payload dict; smoke: (ntfy/send ...) from a jobs schedule delivers (integration smoke with notify.ntfy-delivery)*

SURFACE (one prim, additive – lisp-interpreter.frozen-surface additive rule): (http-post url) ; empty headers, empty body (http-post url headers-json) ; body = \"\" (http-post url headers-json body) ; full form

SEMANTICS: the EXACT http-get contract, send half: - Curl-backed (do_http_get's shape in prims_net.ml): -X POST –data-binary @body_tmp, same temp-file dance, same shell_quote discipline, same -D/-o split. - headers-json: same \"Assoc string->string\" format as http-get; \"_timeout_ms\" reserved header honored the same way (default 20000). - Returns the SAME payload dict VStr: {ok, status, headers, body, err, kind}; 4xx/5xx are returned (kind = http-client-error / http-server-error), never raised. - status=0 / curl transport error RAISES Prim_error transient (design note ?4b), so guard handlers and the jobs runner's attempts/backoff see a real failure. - Effect: Net. Add \"http-post\" to net_prims in lisp/lib/effect.ml (additive tag use; lattice unchanged).

GATE (unchanged from http-get): identity confinement, not host confinement. anonymous -> denied; non-admin, non-*/*agent -> denied (\"admin/agent/human only\"). Rationale carried from http-get: SSRF risk is bounded by who may call, not by a destination allowlist. Host allowlist (PP_HTTP_ALLOW_HOSTS) stays DEFERRED – name it here so nobody thinks it shipped: if outbound http ever opens to non-admin users, an allowlist lands first.

NON-GOALS (v1): http-request general method surface (PUT/PATCH /DELETE) – add when a consumer needs it, same shape; streaming/chunked bodies; connection reuse; a native Eio client replacing curl (the deps for tls-eio already build on the image for remote/'s client, but curl is honest and shipped – port only if curl's process-spawn cost measurably hurts, e.g. notify fan-out loops).

system-browser

The live environment UI: browse branches, functions, types as a place you live
[status: implemented]

> – *agent note:* 2026-08-02: /bindings /pages /types live; ui/nav shell; live GET /bindings?pkg=todo + /pages 200.
>
> *[verify] build: dune build image; smoke: GET / shows user+branch chrome and links to about/functions/repl; smoke: product nav comes from (ui/nav) when shell loaded; not silent OCaml product twin; smoke: product CSS comes from (ui/css) / ui/theme when shell loaded; not silent full OCaml design-system twin; smoke: nav has no /edit/hello; Pages links to /pages; smoke: GET /pages columns: page URL + handler function; smoke: GET /page/hello shows route + handler + callee list; smoke: GET /bindings lists packages including (kernel) and (root)/workspace pkgs; smoke: GET /bindings?pkg=(kernel) lists primitives e.g. create, +; smoke: GET /bindings?pkg=(kernel)&fn=create shows read-only prim docs; smoke: GET /bindings?pkg=todo lists todo/* functions; smoke: GET /bindings?pkg=todo&fn=list shows function detail + edit link; smoke: GET /bindings?q=todo filters; mobile-width usable (nav wraps); smoke: define todo/list + call (todo/list); used-by shows /todos when routed; smoke: function detail shows Callers + Callees panels from shared graph; smoke: function detail links Impact / Changes / Inspect / Edit; smoke: wide desktop: three panes packages|functions|detail when viewport wide*

VOCABULARY (must not conflate): - Page / endpoint = route URL (e.g. /hello) - Function = named binding (e.g. hi-page or todo/list) - Package = in-branch name prefix (todo/), NOT a branch - Branch = versioned code world (system/main) A page RUNS a function; you EDIT functions, OPEN pages. Packages ORGANIZE functions inside one branch.

==========

SMALLTALK COMBO PACK – browser is the hub ==========

Steal five things; they compound through THIS surface:

1. Senders + change impact ? image.inspector 2. Branch change set ? branching.change-set 3. Value + closure inspect ? image.inspector (shipped+) 4. doesNotUnderstand holes ? image.dnu-stubs 5. Three-pane package browser ? THIS section

Shared spine (do not rebuild per feature): - static App-Var graph (collect_var_apps + reverse) - define/install hooks (persist_define + impact + transcript) - AST pretty / inspect routes already on host UI

The browser is where a human or agent LIVES: pick a package, open a function, see callers/callees/routes/impact/holes, jump to edit or inspect, open branch changes. Not five apps.

v1 SHIPPED: - Chrome: whoami, branch, uptime, nav - Home entry points + AI propose form - /about concepts guide - /pages list + /page/<path> inspector - Flat /bindings table (name, effects, author, edit, inspect) - Mobile three-step drilldown (?pkg=&fn=)

FUNCTIONS BROWSER (/bindings) – Smalltalk-ish drilldown:

PHILOSOPHY: - Majority of programs are Nopales bindings in function_defs. - Kernel primitives are OCaml (performant, trusted); still BROWSABLE so the system is legible, but read-only. - Optional future: mark some OCaml modules as "image libs" for hot paths; not required for this cut.

MOBILE FIRST (three-step drilldown, not three columns): URL state via query params (works on phones): Step 1 GET /bindings ? list packages only (big tap targets) Always includes virtual package "(kernel)" Workspace packages from prefix grouping + "(root)" Step 2 GET /bindings?pkg=todo ? list functions in that package Kernel: list prim names in catalog Step 3 GET /bindings?pkg=todo&fn=list ? detail pane (DETAIL CONTRACT below) workspace OR read-only kernel doc (primitives) Back links: Functions ? package ? (back to packages). Mobile stacked drilldown remains canonical at ~390px.

DESKTOP THREE-PANE (combo pack – same URLs, wider layout): When viewport ~900px+, ONE page MAY show three columns: left: packages | middle: functions in pkg | right: detail Selection still ?pkg=&fn= (shareable, no SPA). htmx MAY refresh middle/right; full GET without JS still correct. Do not force three columns on phones.

DETAIL CONTRACT (step 3 / right pane) – compounds the pack: Workspace function_defs always show: - kind, effects, author, updated - source pretty + Inspect AST/JSON - [Edit] ? /edit/<name> - Callers (direct reverse) + Callees (direct forward) from image.inspector shared graph helpers - Used-by routes via used-by-routes on DETAIL only (package index stays handler-direct – no N*depth) - Impact badge if name pending in impact-queue - Holes: unbound App Vars (image.dnu-stubs) + [Stub] - Link to branch Changes when name is own-row override Kernel prims: read-only docs only (no Edit/Stub).

KERNEL CATALOG: - Virtual package name: "(kernel)" (not a real binding prefix) - Source: prim registry + short docs (name, summary, effects) - Kind badge: primitive | function - No Save on primitives; link to About/docs if needed

WORKSPACE (existing + keep): - Group by package_of_name; search q=; author filter - used-by pages; create package+local form - Edit only for function_defs rows

UI SHELL AS LISP (authoritative):

RULE: If a human thinks of it as "the environment UI" (navbar, home workspace, app menus), it is Nopales on a branch – not a parallel OCaml product skin.

- Product shell bindings (required when seed runs): ui/menu – menu tree (prefer zero-arg lambda that returns a list; eager lists are fragile if they call menu/* at define-time) ui/nav – (lambda () (render-html (menu/bar ?))) ui/home – (lambda () ?) home body HTML ui/theme – css/sheet data (tokens + rules); Nopales, not a CSS string blob ui/css – (lambda () (css/render ui/theme)) adapter only; session caches its string - libs/ui/lib.pp seeds system/main (load-library "ui" / seed_stdlib). Personal may pin overrides; inherit main when no pin. Prefer thunks over eager value pins. - Chrome nav uses (ui/nav); GET / uses (ui/home); full-page <style> uses rendered (ui/css) – see image.product-theme. - Identity strip only (brand, username, branch, uptime) stays OCaml – not product structure. - Kernel OCaml pages stay OCaml until deliberately moved: /login, /health, auth middleware, /bindings,/branches, /edit, /inspect, emergency recovery. These are host UI, not a second apps menu. - EMERGENCY chrome (nav/home/theme fail or unbound): minimal, labeled failure (must not look like a healthy product menu or full design system). Silent rich OCaml default_nav / default_home / full inline CSS twin is REJECTED architecture – debt to remove. - Rehydrate load order: parents first, child overrides last (so personal ui/menu can call system menu/link; personal theme/* tokens can override system tokens). - Edit shell via Functions ? package ui (mobile drilldown), including ui/theme and theme/* tokens.

LAYERING SUMMARY: Nopales = the computer you live in (shell + theme + apps) OCaml = host + gate (eval, store, auth, health, emergency)

NAV / ENTRY (combo pack discoverability): - Functions (/bindings) = primary code home - Branches detail ? Changes (branching.change-set) - Optional chrome badge: pending impact count (light) - Unbound handler pages ? Create stub (dnu-stubs)

DEFERRED: - Remove silent default_nav_nodes / default_home_content and shrink html_response style blob to emergency_css (image.product-theme make) - ui/menu seed always lambda (load-order safe by default) - Move softer system pages (/about copy) into Nopales packages - Branch switcher in chrome (detail checkout exists) - Import/require, private symbols, rename-with-rewrite - Authoring new prims from the UI - Dedicated /theme form UI (Functions edit is enough v1; full picker in image.themes)

DATA BROWSER: full CRUD over data_rows is specified in image.data-browser (OCaml system pages, not a Nopales package). /types remains the type_defs index and links into /data/<type>.

TREE BROWSER: lazy zoomable tree UI over the one tree is specified in image.tree-browser (a Nopales package, not OCaml system pages). system-browser stays the code hub (/bindings); tree-browser is the universal *content* face (notes outline, data rows, eventually pkg/type subtrees).

tree-browser

Lazy zoomable tree UI: folders ARE non-leaf nodes; htmx depth-capped expansion; library-first (no kernel prims)

[status: implemented]

> – *agent note:* 2026-08-02: libs/tree tree/page+partial+render-doc; live GET /tree 200.
>
> *[verify] build: dune build image; smoke: GET /tree renders root to depth cap; deeper nodes as collapsed stubs; smoke: GET /partials/tree?slug=?&root=?&depth=2 fragment no chrome; expands stub in place; smoke: folders-only view omits leaf bodies; nodes with children still expandable; smoke: zoom: GET /tree?root=<node-id> re-renders with that node as root; bread-crumb back; smoke: expand returns children + one-level grandchild stubs (no N-requests-for-N-nodes); smoke: no-JS: stub is an <a href> to the same partial URL; full GET still correct; smoke: notes is first root: /tree?slug=<doc> walks the notes outline model; smoke: kernel children-of/subtree + lens prims deferred – BORGE-1785516998 / 1785516993*

THESIS: the one tree (one-tree.tree-model) is not just a storage trick – it is a browseable place. Since outline storage already makes a folder and a title THE SAME THING (a non-leaf node), the UI needs NO folder type: \"folder\" is a VIEW decision (has-children? + collapsed), not a storage one. One renderer walks docs, subtrees, and data.

PRIOR ART: Workflowy/Logseq zoom, Finder/Explorer lazy expansion, Smalltalk hierarchy browser (categories and classes are nodes at different depths). libs/outline/lib.pp ALREADY runs the swap idiom (hx-post /partials/notes-node-op, hx-target #outline, hx-swap outerHTML) – this section generalizes that pattern into a reusable component.

==========

TWO TREES – DO NOT CONFLATE ==========

1. STORE tree (tree_nodes): /sys/pkg/?, /data/<type>/<id>, branch lenses. Kernel addressing; recursive-CTE override walks. NOT the v1 UI surface. 2. CONTENT tree (user-facing outline hierarchy): notes outline nodes, docs ? nodes ? subnodes. The v1 browser walks (2). Store-tree roots come LATER (needs branch-lens-aware read prims; see DEFERRED).

==========

RENDER CONTRACT (pure Nopales, libs/tree) ==========

(tree/render root-id depth folders-only?) -> html string - Recursive walk, depth-capped. Depth x fanout bounds steps, so it fits the 100k sync budget (see multi-user.budgets) – self-limiting by construction. - Node row: twisty + title + child-count badge. - Beyond cap: collapsed STUB, not a leaf. - folders-only?: render only has-children? nodes as rows; leaves appear only as counts.

STUB EXPANSION (htmx, the ONLY async here): <li class=\"tb-stub\" hx-get=\"/partials/tree?root=<id>&depth=2\" hx-trigger=\"click\" hx-swap=\"outerHTML\">? Server returns the expanded SUBTREE FRAGMENT; the stub replaces itself. htmx supplies the client-side async illusion; each server request stays a small synchronous eval. No guest-visible fibers (see lisp-interpreter.language-roadmap: host owns concurrency).

ANTI-PATTERN (do not build): one request per node. Each expansion MUST return children + ONE-LEVEL grandchild stubs, so expansion is instant and request count stays O(user clicks), not O(tree size).

PROGRESSIVE ENHANCEMENT: the stub's hx-get URL is also a plain <a href>; without JS it full-page GETs the same fragment URL (wants_fragment distinguishes). Same discipline as notes.hypermedia-ui.

ZOOM (= \"load this title in the full window\"): GET /tree?root=<node-id> – re-render with the focus node as root. Zoom is ONE parameter, no new mechanism: same renderer, different root. Breadcrumb of ancestors for zoom-out. Zoom is what turns \"folder\" and \"title\" into the same thing from the user's side too.

OOB PATCHING (when zoom/expand affects two panes): hx-swap-oob updates tree panel + content pane in one response. Defer multi-pane until notes dogfood shows the need; v1 single-pane is fine.

==========

WHAT IS NOT HERE (kernel stays still) ==========

- NO new interpreter prims for v1. html/tag, request-param, recursion, and the notes outline model suffice. - NO change to eval budget tiers: depth-cap keeps every request small; that IS the budget story. - Kernel help only WHEN trees get big: children-of / subtree prims over tree_nodes using the materialized path index (one-tree.tree-model PINNED: indexed lookup, not tree walk). Optimization, not v1.

ROOTS ROADMAP (one component, many roots): v1 notes outline (slug root) – dogfood, ships first v1.1 data rows: /tree?root=data:todo (typed-node leaves link into /data/<type>/<id>) v2 store tree: /tree?root=/sys/pkg/notes – needs lens-aware read prims; this is when tree-browser becomes the Smalltalk-style INSPECTOR face for the whole habitat (code ASTs, types, routes as subtrees)

RELATION TO OTHER SECTIONS: - image.system-browser: /bindings stays the code hub; tree-browser is content-first. Shared callers/callees spine untouched. - notes.hypermedia-ui: notes keeps its dedicated outline page; tree-browser is the GENERAL component it can later delegate to. No notes rewrite in v1. - structural-editing.op-protocol: when tree ops (refile/move) land in the browser, they MUST go through the shared tree-op protocol, not ad-hoc routes.

SUCCESS CRITERIA: - A user can browse a deep notes outline without a full page load per level. - \"Folder\" required no schema/type – only a view bit. - Zero kernel changes for the v1 notes root. - Every tree interaction fits the 100k sync budget; no background tier needed for browsing.

data-browser

Generic OCaml system UI for full CRUD over shared data_rows by type

[status: implemented]

[verify] build: dune build image; smoke: GET /data lists types with row counts; shared-data banner present; smoke: GET /data/<type> lists rows (default limit 50) with declared columns; smoke: GET /data/<type>?offset=50

pages next slice; smoke: GET /data/<type>/new shows create form from type_defs fields; smoke: POST /data/<type> creates row from form fields; 303 to detail; smoke: GET /data/<type>/<id> shows fields + edit form + delete; smoke: POST /data/<type>/<id> updates fields; 303/reload detail; smoke: POST /data/<type>/<id>/delete deletes row; 303 to type list; smoke: GET /types links each type to /data/<type>; smoke: GET /inspect/row/<type>/<id> redirects or aliases to /data/<type>/<id>; smoke: type with no type_defs fields still allows raw JSON create/edit; smoke: extra jsonb keys not in type_defs still shown on detail

WHY: /types shows declared shapes; /inspect/row dumps one row as pretty JSON. Neither is a place to live in the object store. Product packages (todo, notes, bible) have purpose-built UIs, but agents and humans still need a generic browser when there is no package UI, the package is broken, or the type is ad-hoc.

LAYERING (locked): - OCaml system pages in image/lib/http.ml (+ thin helpers in crud.ml / store.ml as needed). Host/gate tier – same as /types, /bindings, /inspect, /edit. - NOT a Nopales package. Product shell stays Nopales; this is emergency/generic substrate UI that must work with empty or broken gardens. - Mutations call existing Crud/Store SQL paths. Do not invent a second data access layer. - data_rows are SHARED across branches (no branch_id). UI must say so on every list/detail surface.

==========

ROUTES (full CRUD) ==========

Index (Read types + counts): GET /data - Table: type_name | declared fields | row count | link - Types = visible type_defs on current branch (Store.list_types) - Also surface type_names that have data_rows but no type_def (orphan data) so nothing is invisible - Banner: "Data rows are shared across branches" - Link back/forward with /types (types = schema index; /data = instances)

List (Read many): GET /data/<type> - Query: limit (default 50, max 200), offset (default 0) - Columns: id (short) + each declared field (truncated) + updated_at if cheap; link id ? detail - Pagination: Prev / Next when more rows exist - Actions: [New row] ? /data/<type>/new - Empty state: no rows yet + create CTA - Order: created_at ASC (match Crud.list) unless a later plan picks something smarter

Create: GET /data/<type>/new - Form: one input per declared field (text inputs v1) - If type has ZERO declared fields OR user wants freeform: textarea name=fields_json for raw JSON object - POST target: /data/<type> POST /data/<type> - Content-Type application/x-www-form-urlencoded - Build fields jsonb from declared field names present in the form; if fields_json posted and non-empty, that wins (power path) - author = Session username - On success: 303 Location: /data/<type>/<id> - On failure: 400 with error card + back link

Detail / Update / Delete: GET /data/<type>/<id> - Show all fields (declared first, then extra jsonb keys not in type_defs – do not hide unknowns) - Edit form prefilled (same field rules as create) - Delete form POST /data/<type>/<id>/delete (confirm via button label; no JS required) - Meta: id, type, author, created_at, updated_at when available - Links: back to type list, /types, REPL hint POST /data/<type>/<id> - Update fields (full replace of fields jsonb from form, same merge rules as create). Uses Crud.update path. - 303 back to detail on success POST /data/<type>/<id>/delete - Crud.delete; 303 to /data/<type> - Missing row: 404 card, not silent success

URL parsing notes: - type_name may contain only safe path segments in v1 (letters, digits, hyphen, underscore). Reject or 400 weird paths; no path-param injection into SQL (always parameterized – already true in Crud). - id is UUID string. - Prefer longest-match dispatch: /data/<type>/new /data/<type>/<id>/delete /data/<type>/<id> /data/<type> /data so "new" is never treated as an id.

==========

FIELD / JSON RULES (v1) ==========
- type_defs.fields is a JSON array of field-name strings (no field types yet – object-model.type-system deferred). - Form values are strings; store as JSON strings in the fields object. Do NOT guess number/bool coercion in v1 unless the existing value is already that shape and a later polish wants round-trip fidelity. - Raw JSON textarea: must parse as a JSON object; reject arrays/scalars with a clear error. - Extra keys on existing rows: display on detail; include in edit form as additional inputs OR preserve via hidden merge so update does not drop them. REQUIRED: updates must not silently strip unknown keys.

==========
RELATIONSHIP TO EXISTING PAGES ==========
- /types: keep as type_defs browser; each row links to /data/<type>. Optional: add row count column on /types once count helper exists (nice-to-have, not blocking). - /inspect/row/<type>/<id>: redirect (302/303) to /data/<type>/<id> OR thin alias rendering the same page. Prefer redirect so one canonical URL. - Product apps unchanged: /todos, /notes, /bible stay Nopales. - Nav: emergency/system links may include Data ? /data; product ui/menu MAY add Data later (Nopales choice, not required for make).

==========
STORE / CRUD HELPERS (implementation discretion) ==========
Add only what the UI needs if missing: - count rows by type_name (for index) - list type_names present in data_rows (orphans) - list rows with limit+offset (Crud.list today is limit-only; extend with offset or a store helper) - optional: fetch author/created_at/updated_at for detail Keep Nopales prim surface stable unless a prim gap blocks the browser (prefer OCaml-only helpers for offset/count).

==========
AUTH / SAFETY ==========
- Same session gate as other authenticated system pages. - Not admin-only in v1 (any logged-in user can browse/mutate shared data – matches Nopales CRUD prims today). - No CSRF token infrastructure in v1 (status quo for other POSTs); cookie session + same-site assumptions hold. - Never interpolate type/id into SQL strings.

==========
NON-GOALS (v1) ==========
- Field type system / validation beyond JSON object shape - Full-text search UI (find-text exists for Nopales; wire later) - Inline htmx row edit without full page (optional polish) - Bulk delete / CSV import-export - Per-row branch scoping (data is shared by design) - Nopales-redefinable browser UI - SPA / client-side routing

==========
ACCEPTANCE NARRATIVE ==========
Human can: open /data ? pick a type ? page through rows ? open a row ? edit a field ? save ? create a new row ? delete a row ? land back on the type list. All without REPL. Agent can use the same URLs or keep using CRUD prims.

page-timing

Per-route page render timing

[status: implemented]

> *[verify] build: dune build image; smoke: GET /timing lists each user route with count + avg db_ms/total_ms (empty/zero-safe when no samples); smoke: GET /<route> twice then GET /timing shows count=2 for that route; smoke: each handled route response carries X-Timing-Ms header; smoke: GET /timing sorts slowest-first by max_ms; shows db_vs_total split; smoke: /timing 404-safe / zero-safe with no routes ever handled*

WHY: Product pages are Nopales route handlers, and there is no first-class answer to "how long does each page take to load?". Hand-wrapping every handler with (now-ms) deltas is repetitive and easy to forget. A single choke point already exists – every handled user route flows through Session.call_handler – so we can measure universally with no per-package work.

WHAT WE MEASURE (server-side render time, not client perceived): - total_ms: wall time of the handler call (handler body only, not HTTP write-back) - db_ms: accumulated time inside DB-touching CRUD prims during that handler - db_hits: count of DB-touching prim calls during that handler - at: wall clock (epoch ms) the sample was taken - route: the handler name/path This is the cost to PRODUCE the page in the image. It is NOT full end-to-end (network/TLS/browser paint). End-to-end measurement is explicitly out of scope here (needs client Navigation-Timing POST; deferred).

MEASUREMENT 1. Budget accumulation (lisp/lib/eval.ml): budget currently tracks prim_calls + db_hits but not DB wall time. Add a mutable db_ms : float to the budget struct (init 0.0). prims_db.ml register_crud already computes elapsed_ms per prim; change ‘ignore _elapsed_ms‘ to accumulate it into the budget via a helper (mirroring note_db_hit, e.g. note_db_ms on current_budget). This is the "future function_stat.db_time_ms aggregation" the existing comment already earmarks. 2. Choke-point capture (image/lib/http.ml): every call to Session.call_handler (both dispatch sites: the launch_user_route_or path and the /data-adjacent user route path) is wrapped so BEFORE the call we read the current eval budget's db_ms/db_hits, and AFTER we read now-ms and the ending budget. One clean helper Timing.measure f that runs the handler, then records a sample { route; total_ms; db_ms; db_hits; at }. A handler that fails still records its sample (the work happened); the failure path is unchanged otherwise. 3. Sample store (image/lib: new timing.ml, mirroring the data-browser pattern): a small in-process sample ring per handler name. Keep a bounded window (e.g. last 1000 samples overall, or last 100 per route) to avoid unbounded growth. Optionally mirror into data_rows as type ‘page_timing‘ for cross-restart persistence + Nopales querying – a nice-to-have, no migration required; in-process ring satisfies /timing + header with none. Persistence deferred unless we want history across restarts.

SURFACE 1. /timing system page (OCaml dispatch entry mirroring /branches, /data): table per route name – samples | last_ms | avg_ms | max_ms | db_ms | db_hits | db_share (% of avg total). Sorted by max_ms descending (slowest first). Empty/zero-safe when there are no samples. 2. X-Timing-Ms response header: attach total_ms to every handled-route response (in respond_handler_value / the response path) so a browser or curl can see the number per request without opening /timing.

SCOPE / NON-GOALS - Server-side render time ONLY. No client Navigation-Timing end-to-end measurement (deferred, not this one). - No new schema in v1 (in-process ring); data_rows ‘page_timing‘ persistence is optional/deferred. - kernel paths (/data /admin /api/eval ?) are NOT measured: only user route handlers (the product pages people ask "how long does this page take" about). - /timing is a private system page (auth-required, like /branches), not a public route.

ACCEPTANCE NARRATIVE Human: open a few pages, then GET /timing ? see each page with count + slowest-first order + DB share; curl -i a page ? see X-Timing-Ms on the response. No per-package code needed to be measured.

product-theme

Product presentation as Nopales data: css/* sheet compiler, ui/theme + ui/css, emergency CSS only in OCaml

[status: implemented]

[verify] build: dune build image; smoke: (css/render (css/sheet (body margin 0 background "#d4d0c8"))) contains body{ and margin:0; smoke: (function-source "ui/theme") or (function-source "ui/css") non-empty after seed; smoke: (export-package "ui") contains define ui/theme or define ui/css; smoke: GET / authenticated response <style> matches rendered (ui/css) distinctive marker, not only emergency; smoke: personal (define theme/bg ?) or ui/theme pin changes next full-page CSS; checkout main restores; smoke: (define ui/css (lambda () (error "boom"))) still serves page with emergency CSS + labeled failure; smoke: htmx fragment / partial responses do not re-inject full stylesheet; smoke: login page stays pre-session OCaml mini stylesheet (no Nopales theme required)

WHY: Today almost all product CSS is a giant inline string in image/lib/http.ml html_response – inaccessible from the garden, unversioned as Nopales, dual to the product-shell rule that already moved nav/home into libs/ui. Widget packages emit class names that only work because that OCaml blob knows them. That is a black box.

DECISION (Path B – honest Nopales): Presentation is Nopales data, same substrate as shell and apps. A small css/* compiler (sibling of html/* in std) turns sheets into CSS text. ui/theme holds the sheet; ui/css is a thin (lambda () (css/render ui/theme)) adapter for session refresh. Humans and agents edit sexps / tokens via Functions – not escaped CSS inside a lambda, and not a second language document as the native store.

REJECTED: - Path hybrid: (define ui/css (lambda () "body{?}")) as the primary form (CSS-in-string wearing Nopales hat) - Path A as native store: bare CSS document / data_rows stylesheet type as the only theme representation (allowed later as import/export sugar, not authority) - Static /assets/*.css as the product theme path - Silent full OCaml design-system twin beside Nopales theme - Per-request uncached re-eval of ui/css without shell refresh discipline (mirror ui/nav caching lessons) - TIME-BASED STALENESS: a TTL on the shell cache serves wrong CSS for up to a minute for no correctness reason (supersedes the earlier 60s TTL; invalidation is now dependency-tracked, below) - GENERAL USER-FUNCTION MEMOIZATION: Nopales functions may read DB or request state mid-eval, so same-args-does-not- imply-same-output; no purity story in the type system yet. Caching applies to the zero-arg shell bindings ONLY.

==========

css/* (libs/std/lib.pp – seed with std, before ui) ==========

Parallel to html/*: structure in Nopales, render to string.

Core bindings (v1 – keep small): (css/sheet rule?) ? sheet value (list-tagged data) (css/use other) ? splice/concat another sheet (css/raw "?") ? escape hatch for rare CSS (css/render sheet) ? CSS string

Rule encoding (selectors as strings; declarations data): - (selector prop val prop val?) selector may be a symbol (body, header) or string (".card", "nav a", "details.ol-node > .ol-sum") - ((sel1 sel2 ?) prop val ?) multi-selector group ? "sel1, sel2 { ? }" - ((media "max-width:40rem") rule?) nested @media block - Values: number | string | symbol (symbol resolves as token binding if bound, else as CSS ident) - Do NOT invent a full selector AST or px-type system in v1. Selectors stay strings/symbols; props are alternating key/value data.

Emit rules (css/render): - prop symbols/strings ? CSS property names (margin ? margin; font-family ? font-family; accept underscore?hyphen if needed) - numbers: print without quotes (0, 1.4) - strings: as CSS values (caller includes units) - stable, readable output; order preserved - css/raw segments pass through unchanged

Composition: (css/sheet (css/use ui/theme-base) (css/use todo/theme) ; optional later (body background theme/bg))

html/* analogy docstring in std: "sheets ? css/render; no raw rule soup in apps" (css/raw remains the deliberate guest).

==========

ui/theme + tokens + ui/css (libs/ui/lib.pp) ==========

Required product-shell bindings (with ui/menu ui/nav ui/home):

theme/* tokens (examples; exact set is implementation discretion so long as the classic-Mac look ports): theme/bg theme/ink theme/panel theme/chrome theme/link theme/err theme/ok ?

ui/theme A css/sheet (or zero-arg lambda returning a sheet) expressing the full product design system currently hard-coded in http.ml (body, header, nav, cards, tables, forms, outline, todos, calendar, bible, weather class contracts, mobile breakpoints). Prefer data + theme/* tokens over magic hex literals so personal gardens can (define theme/bg ?).

ui/css (lambda () (css/render ui/theme)) or (lambda () (css/render (ui/theme))) if theme is a thunk. Adapter only – not where humans paste CSS.

Class contract: - Shared classes used by multiple packages live in ui/theme (todo-box, ol-node, cal-grid, card, ?). - Package-local extras may keep a small (html/tag "style" ?) or later (todo/theme) composed via css/use – weather/style today is acceptable local. - Moving the monolith out of OCaml does not require splitting packages on day one.

Seed: seed_stdlib still load-library std then weather then ui ? – css/* must exist before ui/theme renders. (std before ui already holds.)

==========

Session cache + HTTP inject ==========

Mirror ui/nav:

Session.t gains mutable ui_css : string option Some s ? product stylesheet text None ? use emergency_css

refresh_ui_shell (rename meaning: refresh shell): existing (ui/nav) path unchanged plus eval (ui/css) ? string | raw-html-as-text ? cache; on miss/throw ? ui_css <- None

Invalidate / refresh – DEPENDENCY-TRACKED, not guessed: At each shell render, the kernel records the set of bindings (ui/css) / (ui/nav) actually resolve during eval (env read-set, e.g. theme/vars, ui/theme, ui/theme-nav, notes/tree-css, theme/bg, ...). A define busts the cache IFF the defined name is in that recorded set – theme/extra busts (it's read), todo/foo doesn't (it isn't). No TTL, no name-prefix heuristic: the cache is fresh forever until a real dependency changes. checkout / branch switch still busts unconditionally (no stale other-branch CSS; read-sets are per-branch). load-library still refreshes at end (eval_form path) since bulk redefines legitimately change the read-set. Shell evals cause ZERO DB WRITES: budget-stats persistence (function_stat) MUST skip shell labels (ui/css ui/nav ui/home ui/theme) – the shell refresh runs in the request gate and must not turn into a serialized Crud.create under the pgx sequencer.

html_response gains ~css parameter (or reads session): HTML.style [] "%s" css Authenticated full pages pass Session.ui_css | emergency_css.

fragment_response / HX partials: do NOT re-inject the full stylesheet (page already has it). Same spirit as chrome-skip for fragments.

login_form_page (pre-session): keeps a tiny OCaml-only mini stylesheet. Must not require Nopales theme. Not the product design system.

==========

Emergency CSS (OCaml kernel – labeled, minimal) ==========

emergency_css is host recovery, not a product twin: - monospace / high-contrast / readable - styles emergency-banner, emergency-nav, basic links - MUST look broken or sparse on purpose if product theme fails (parallel emergency-nav rule) - After make: the 200-line classic-Mac blob MUST leave html_response; only emergency_css (+ login mini) remain as OCaml string stylesheets.

Optional: when falling back, surface a one-line labeled banner in chrome ("product theme unbound – emergency css") consistent with emergency-nav labeling.

==========

Authoring / multi-user / sync ==========

- Edit via Functions ? package ui ? ui/theme | theme/* (same mobile drill-

down as other shell bindings). - Personal pin: (define theme/bg "#e8f0e8") or full ui/theme override on user/personal; inherits main when no pin. - (export-package "ui") includes theme tokens + ui/theme + ui/css; pp_sync pull/push works unchanged. - Agents: pp_eval define/function-source – no new REST. - v1 non-goals: /theme textarea page, CSS file import pipeline, Tailwind/Sass build step, data_rows theme type as authority, per-user CSS without branch pins.

==========

MAKE ORDER ==========

1. css/* in libs/std + unit/smoke sexp?CSS 2. Transcribe http.ml product blob ? ui/theme (+ tokens) in libs/ui; define ui/css adapter 3. Session ui_css + refresh_ui_shell extension 4. html_response ~css inject from session 5. Shrink OCaml to emergency_css (+ login mini) 6. Smokes: seed marker, personal override, failure fallback, fragment no-reinject 7. borge drift / resolve HTTP robustness verification

STATUS: planned until make lands and silent full OCaml product CSS twin is gone.

themes

Installable, switchable named themes: a theme is a libs/<name> package of theme/* tokens; switch = reseed into your garden; registry is a Nopales list, no kernel tables

[status: implemented]

> *[verify] build: dune build image; smoke: (theme/available) lists the default token package with display name + description; smoke: (theme/current) reports the active theme on the current branch; fresh garden reports the default; smoke: (theme/set "<name>") switches the garden: next full-page <style> shows the new theme's distinctive token values; smoke: switch replaces ALL pinned theme/* tokens on the current branch (no stale-token bleed from the previous theme); smoke: switch leaves a personal ui/theme sheet override intact; tokens flow through it; smoke: other users' themes unchanged by my switch; checkout main shows system defaults; smoke: (theme/set "<unregistered>") is a labeled error; active theme unchanged; smoke: GET /settings/theme lists available themes, marks current, applies switch without manual source editing*

WHY: product-theme made presentation Nopales data (css/* + ui/theme + theme/* tokens) and branch pins already make token override possible – but only by hand-editing twelve theme/* defines through Functions. Nobody will do that. The missing product surface is: named themes you can install and switch between as one act, per user, without touching source.

==========

MODEL – a theme is a PACKAGE, not a row or a table ==========

A theme is a Nopales package libs/<theme>/lib.pp whose entire job is defining theme/* token bindings (the existing libs/theme token set: theme/bg theme/ink theme/panel theme/chrome theme/link theme/visited theme/muted theme/err theme/ok theme/border theme/row-alt theme/shadow). A theme package MAY also carry a full ui/theme sheet override, but v1 themes are token-only: the shared ui/theme sheet reads tokens, so swapping tokens reskins the whole product.

Nothing new in the kernel. Install = the package exists in the vault (or was defined live). Switch = the theme's token defines land on YOUR branch as pins (standard branching.package-updates semantics: garden pins shadow system/main; checkout main restores system defaults). Per-user themes fall out of per-user branches – no per-user preference table, no cookie, no data_rows setting (all REJECTED: preference state must live in the same branch/version/promote substrate as every other user choice).

==========
REGISTRY – Nopales data, not a kernel catalog ==========
The registry is itself a binding in the theme package:

theme/available (lambda ()) -> list of alist-ish dicts, one per installed theme: name, display, description, (optional) author. Source of truth for the picker. Default seed ships the system token package as the one entry.

theme/current (lambda ()) -> name string. v1 derivation: the garden's own binding theme/name if a switch pinned it, else the system default name. (Honest label, not a guess from token values.)

theme/set NAME -> switches the CURRENT branch to theme NAME: looks NAME up in theme/available, evaluates the named theme package's token defines as pins on the current branch (same code path as reseed-package, narrowed to theme/* + theme/name), then triggers the existing ui/css shell refresh so the next full-page response carries the new sheet. Unknown name -> labeled error, no partial switch. Switch is ALL-OR-NOTHING across the token set: a theme that defines only some tokens inherits the ACTIVE theme's remainder at switch time (pins are written for every token), never whatever random pin was already on the branch – no stale-token bleed between switches.

Installing a new theme = adding libs/<name>/lib.pp to the vault plus one entry in theme/available (promote to system/main to share; keep on personal to hoard). pp-sync snapshot/pull treats themes like any package. Agents: pp_eval (theme/set \"phosphor\") – no new REST.

==========
PICKER – /settings/theme (Nopales route, libs/ui) ==========
A small settings page (private route, same discipline as other product routes): lists theme/available entries as cards (display name, description, swatch row rendered inline from each entry's token values), marks theme/current, and POSTs a switch via htmx to a partial that calls (theme/set name) and returns the updated card list; the next FULL page load shows the new theme (fragment responses never re-inject the stylesheet – existing product-theme rule). No-JS fallback: plain form POST + redirect to /settings/theme.

INTERACTION WITH PERSONAL ui/theme PINS: A garden that pinned its own ui/theme sheet keeps it – theme/set only touches theme/* + theme/name. Tokens flow through whatever sheet is visible. A theme that ships a sheet override installs it as a pin too, and switching AWAY removes that pin (restores inherited ui/theme). Sheet-carrying themes are flagged in their registry entry so the picker can say so.

REJECTED: - data_rows theme/preference entities as authority (shadow state outside branch semantics – the exact thing product-theme rejected for CSS itself) - Static /assets/<theme>.css files (rejected in product-theme already; stays rejected) - Kernel theme catalog table / migration (catalog is Nopales data on branches, versioned like code) - Live preview without switch (v1: swatch row only; real preview is switch-then-look, checkout restores) - Theme inheritance/chaining beyond token fallback - Per-page or per-app themes (one active theme per branch, period)

RELATION TO product-theme: This section changes NOTHING about css/*, ui/theme, ui/css, session caching, or emergency CSS. It adds the registry + switch + picker on top. The deferred "Dedicated /theme form UI" line in the htmx-interface overview resolves to THIS section's picker.

MAKE ORDER: 1. theme/name + theme/available + theme/current + theme/set in libs/theme (switch via narrowed reseed path; all-or-nothing token pins) 2. /settings/theme + /partials/theme-switch in libs/ui 3. Smokes per verify stanzas

packages

In-branch prefix packages for organizing functions (not branch ownership)

[status: verified]

[verify] build: dune build lisp image; smoke: reader accepts symbol todo/list as Var; smoke: (define todo/list (lambda () 1)) then (todo/list) => 1; smoke: todo/list and calendar/list coexist on same branch; smoke: /bindings groups todo/list under package todo; smoke: (load-string "(define pack/x (lambda () 7))") then (pack/x) => 7; smoke: (load-library "todo") installs /todos and todo/page; smoke: libs/todo/lib.pp is source of truth; no OCaml string recipe body; smoke: (load-library "bible") defines bible/verse bible/chapter bible/page + /bible; smoke: after seed: (bible/verse "John" 3 16) returns BSB text containing God/world; smoke: GET /bible?book=John&chapter=3 lists verse text; smoke: GET /bible?ref=BSB:John:3:16 focuses that verse; smoke: seed script idempotent: second run does not duplicate refs; smoke: (function-source "ui/nav") returns non-empty lambda/list source; smoke: (export-package "ui") contains define ui/nav; smoke: (function-source "ui/css") or ui/theme non-empty after seed; export-package ui includes theme; smoke: scripts/pp_sync.py status ui exits 0 with env set

PROBLEM: flat binding names collide once many tools live on one branch (todo list vs calendar list).

MODEL (v1): - Package is a PREFIX of a function name, separator '/'. - Full binding key remains (branch_id, name) with name the full string "todo/list". No packages table required. - package_of_name "todo/list" = "todo"; local = "list". - package_of_name "todo/ui/row" = "todo/ui"; local = "row". - package_of_name "hi-page" = "" (root). - Call and define use the full name: (todo/list), (define todo/list ?). - Pages still route to full handler names: (route "/todos" "todo/list").

ORTHOGONAL TO BRANCHES: - Branch = version + ownership (multi-user.namespaces). - Package = organization inside one branch. - UI must never call a branch a "package" or vice versa.

NOT IN V1: - (require 'todo) / import aliases - Private package symbols - Automatic rename of call sites - Cross-branch qualified names (system/main:greet) – still multi-user.namespaces deferred item - Privileged global package registry

AI / EDITOR: - Prefer namespaced names for new tools (todo/list not list). - AI propose form: optional package field + local name, or single name field that may contain /. - Function editor URL remains /edit/<full-name> with / in the path segment (encode if needed) or query name=; implementation may use /edit?name=todo/list if path routing is awkward – pick one and document in agent note.

LIBRARY LOADER (implemented): Same Nopales source text in git repos and in the live system. OCaml provides only a pure loader (no app string blobs).

On-disk layout (shipped in release tarball as libs/): libs/std/lib.pp – list/*, html/*, css/*, menu/*, data/* libs/todo/lib.pp – deftype + todo/* + routes + partials libs/hello/lib.pp – optional hi-page recipe as Nopales libs/bible/lib.pp – bible/* API + /bible (canon is data_rows) libs/ui/lib.pp – ui/menu ui/nav ui/home ui/theme ui/css libs/ai/lib.pp – ai/ask ai/do wrappers libs/chat/lib.pp – multi-user lobby+DM (multi-user.chat) libs/plan/lib.pp – Unix .plan status (multi-user.user-plan)

Loader API: (load-string SRC) read_all forms; eval_one each (define persists via existing intercept; route/ deftype via prims). Stop on first error. (load-library NAME) load file libs/<NAME>/lib.pp relative to PP_LIBS_DIR or ./libs (release CWD).

Boot / recipes: seed_stdlib ? load-library "std" then "ui" then "ai" then (when present) "chat" and "plan" for multi-user social recipe_todo ? load-library "todo" recipe_hello ? load-library "hello" recipe_bible ? load-library "bible" (types+fns+route ONLY; does NOT bulk-insert verses)

Release build MUST copy libs/ into the tarball.

==========

LIBRARY SYNC CLI ==========

PROBLEM: live function_defs drift from git libs/*.pp when users or AI edit in

the browser. Push of kernel does NOT overwrite DB. Developers need explicit sync so laptop git matches language state.

MODEL: - Local truth for recipes: libs/<pkg>/lib.pp - Live truth for running language: function_defs on current branch - CLI (scripts/pp_sync.py) uses authenticated /api/eval (pp_eval) and export prims – no direct Postgres from laptop required.

EXPORT PRIMS (image): (function-source "ui/menu") ? VStr pretty body only (lambda/list/?) for define (export-package "ui") ? VStr multi-form lib.pp text: ;; package ui – exported from live branch (define ui/menu ?) (define ui/nav ?) ? sorted by name Root package "" / "(root)" exports unprefixed names only. Kernel prims are never exported. (package-bindings "ui") ? VList of VStr full names in that package on this branch

CLI: scripts/pp_sync.py status [pkg] Compare libs/<pkg>/lib.pp define names vs live package-bindings. Report only-local / only-live / both (optional body hash later). scripts/pp_sync.py pull <pkg> Write libs/<pkg>/lib.pp from (export-package pkg). Creates directory if missing. Does not auto-commit git. scripts/pp_sync.py push <pkg> (load-library pkg) via pp_eval – file ? live (upsert defines). scripts/pp_sync.py pull-all Pull every non-empty package that exists live or under libs/.

ENV: same as pp_eval (PP_URL PP_USER PP_PASS, ~/.config/pricklypear/env).

OUT OF SCOPE v1: - data_rows sync (todos/bible text) - automatic merge conflict resolution - function revision history table - Doltgres

VERIFY: - (export-package "ui") contains define ui/nav - pull ui rewrites libs/ui/lib.pp; status shows both - push ui after edit reloads live

==========

BIBLE LIBRARY (BSB dogfood) ==========

GOAL: read BSB from the live image via Nopales + /bible page. Canon lives in Postgres data_rows (shared across branches). Functions live in package bible/ via load-library.

DECISIONS: - Translation v1: BSB only (attribution in page footer / lib header). - Storage: data_rows, NOT giant define / NOT .sexp corpus at runtime. - Ref string (human + share + seed key): BSB:<Abbrev>:<chapter>:<verse> e.g. BSB:John:3:16 BSB:1Cor:13:4 BSB:Ps:23:1 - Book token in ref = stable ABBREV (no spaces). Display name on bible-book rows separately. - data_rows.id stays UUID PK (migration 003). Ref is NOT the PK. fields.ref holds BSB:Abbrev:C:V uniquely. - Optional seed optimization: deterministic UUID v5 from ref so tooling can recompute id; Nopales users still call bible/* not raw get-by-uuid. Either UUID-default or v5 is fine if ref unique.

TYPES (deftype from libs/bible/lib.pp): bible-book: name, abbrev, ordinal, testament (~66 rows; menus / prev-next / name?abbrev map) bible-verse: translation, book, abbrev, chapter, verse, text, ref chapter/verse as JSON numbers or digit strings – pick one in seed and stick to it (prefer numbers in JSON). ref = "BSB:John:3:16" always.

LOOKUP (needs more than blind rows scan): (get 'bible-verse uuid) alone is not enough for humans. Provide ONE of (make picks; prefer smallest): A. Crud/store helper + prim: (find-row 'bible-verse "ref" "BSB:John:3:16") (find-rows 'bible-verse "abbrev" "John" ["chapter" 3]) ; chapter list B. Dedicated thin prims bible-get-ref / bible-chapter (worse – special-case kernel). Prefer A (general field find). GIN on fields already exists; add UNIQUE index for idempotent seed: CREATE UNIQUE INDEX data_rows_bible_ref_uidx ON data_rows ((fields->>'ref')) WHERE type_name = 'bible-verse'; (migration 004 additive – only if make needs it).

LISP API (libs/bible/lib.pp): (bible/ref book chapter verse) -> "BSB:John:3:16" book may be name or abbrev; normalize via bible-book catalog (bible/verse book chapter verse) -> text VStr | VNil (bible/verse-row book chapter verse) -> fields JSON VStr | VNil (bible/chapter book chapter) -> VList of verse fields/sexps (bible/books) -> list from bible-book rows ordered by ordinal (bible/search q) -> VList hits (v1: SQL ILIKE or limited scan; may be prim-

backed; OK if slow/limited first cut) (bible/page) -> GET renders chapter; POST goto redirects (route "/bible" "bible/page")

URL SURFACE (exact path /bible only – no path params in v1): GET /bible GET /bible?book=John&chapter=3 GET /bible?book=John&chapter=3&verse=16 GET /bible?ref=BSB:John:3:16 GET /bible?q=love (optional search) POST /bible book= & chapter= & verse= -> redirect to GET with query (PRG) Do NOT require colon-ids in path segments. ref= query is the shareable explicit form (URL-ok in query).

ABBREV TABLE (seed must use these tokens in ref): Gen Exod Lev Num Deut Josh Judg Ruth 1Sam 2Sam 1Kgs 2Kgs 1Chr 2Chr Ezra Neh Esth Job Ps Prov Eccl Song Isa Jer Lam Ezek Dan Hos Joel Amos Obad Jonah Mic Nah Hab Zeph Hag Zech Mal Matt Mark Luke John Acts Rom 1Cor 2Cor Gal Eph Phil Col 1Thess 2Thess 1Tim 2Tim Titus Phlm Heb Jas 1Pet 2Pet 1John 2John 3John Jude Rev (If vendor data uses different codes, map in seed script; document mapping next to script. Display names full English.)

BULK SEED SCRIPT (required – not HTTP recipe): Path: scripts/seed_bible_bsb.py (or .ksh driver + py) Inputs: - BSB source file(s) (JSON/CSV/USFM – vendor format; script owns parsing; do not commit illegal redistrib if license forbids; prefer redistributable BSB dump + NOTICE) - PG connect: same as dev (PP_DB_* / /tmp:5433) Behavior: 1. Ensure type_defs exist OR document that load-library bible must run first (deftype). Prefer: script can INSERT type_defs rows for bible-book/bible-verse if missing (author system). 2. Upsert ~66 bible-book rows (stable id or fields.abbrev unique). 3. Upsert all bible-verse rows: fields.ref unique; ON CONFLICT DO UPDATE text (requires unique index on ref – migration or special conflict target). 4. Idempotent: second run = no duplicate verses. 5. Print counts: books N, verses M. NOT in recipe_bible HTTP handler (too slow / wrong layer).

INSTALL STORY: A. scripts/seed_bible_bsb.py # once per DB B. (load-library "bible") # or POST /api/recipe/bible C. (bible/verse "John" 3 16) D. open /bible?book=John&chapter=3

HOME UI (optional make): Card "Install bible library" -> POST /api/recipe/bible Note on card: "Run seed script for BSB text if empty".

RENDER: v1: simple HTML chapter list + optional verse highlight is OK. Optional: ?view=sexp returns chapter as Nopales list via bare value. Attribution footer: Berean Standard Bible / license line.

PERSONAL LAYER: notes/bookmarks are NOT bible/dabar – a separate module owns them. Canon text stays shared.

MAKE CHECKLIST: 1. Abbrev map + seed script I/O against sample or full BSB 2. migration 004 unique index on verse ref (if upsert needs it) 3. find-row / find-rows (or equivalent) for ref + chapter 4. libs/bible/lib.pp API + route /bible 5. recipe_bible + optional home card 6. Smokes in verify stanza above

OUT OF SCOPE V1: - multi-translation UI - path params /bible/John/3/16 (map later from same ref) - full-text search engine - audio / cross-refs apparatus - pure-sexp file corpus as runtime source of truth

DEFERRED (packages general): library_files table, git export, multi-file manifests, load from HTTP.

Kernel prims (OCaml) stay under (kernel) browser package. Majority of app code remains Nopales in .pp files.

browser-repl

Evaluate Nopales from the browser against the live session env

[status: implemented]

> *[verify] build: dune build image; smoke: POST /api/eval (+ 20 22) => 42; define + call persists*

- GET /repl – input + Eval button - POST /api/eval {expr} -> {ok,value|error} - Same Session.eval_one path as SSH REPL - Not a second interpreter

function-editor

Load, edit, and save a binding's AST from the UI
[status: implemented]

> – *agent note:* 2026-08-02: textarea editor + missing_editor_card + /api/edit/create; live GET /edit/no-such-fn-xyz shows does not exist + Create.
>
> *[verify] build: dune build image; smoke: POST /edit/editor-greet save -> callable via /api/eval; smoke: GET /edit/missing-fn shows create affordance, not silent TODO only; smoke: GET /edit/hello after hello-recipe: offers Edit hi-page + Create hello; smoke: htmx POST create missing fn returns editor partial; save works*

URL: /edit/<function-name> (function name, NEVER a route path as the object of edit – routes are pages).

v1 SHIPPED: plain textarea editor + save on current branch when the binding already exists.

REQUIRED NEXT – missing binding empty state: When GET /edit/<name> and no function_defs row for name:

1. Do NOT present only a raw TODO stub as if the user is already editing a real function.
2. Show an explicit card: Function "<name>" does not exist.
3. Route awareness: if a page route "/<name>" (or path equal to name) exists with handler H: There is a page /<name> that currently runs function H. Primary: [Edit H] -> /edit/H Secondary:[Create function <name>] Optional: [Create <name> and point /<name> at it] (define + route update; power move) If no such route: only Create (and link back to Functions).
4. Create-in-place via htmx (no full-page dead end): POST /api/edit/create {name} (and optional rebind_route) -> 200 HTML partial: the editor form for the new binding (same fields as GET /edit/<name> after create) hx-target=#editor-root hx-swap=innerHTML Default body stub: (lambda ()\n "TODO: implement <name>") After create, user saves via existing POST /edit/<name>.
5. Creating a function does not silently rename routes unless the user chose "point page at it".
6. Namespaced names (image.packages): - Accept full names with '/' (todo/list) in name field. - Create form MAY split package + local name and join with '/'. - URL routing for /edit/todo/list: either path segments after /edit/ joined back to todo/list, or /edit?name=todo%2Flist. Prefer path join if http router is easy; document choice.

DEFERRED: optimistic concurrency / stale-body reject. The structural AST tree-editor now lives in structural-editing.ast-structure-view (paths first; stable node storage still via branching.ast-nodes).

inspector

Inspect values, rows, ASTs, and page?function graphs live
[status: implemented]

> – *agent note:* 2026-08-02: /inspect/binding, callees/callers/holes/impact-queue prims; live (callees "ui/nav") ? ui/menu menu/bar; inspect page 200.
>
> *[verify] build: dune build image; smoke: GET /inspect/binding/<name> shows author + AST; smoke: GET /page/hello after recipe: handler hi-page listed; smoke: page inspector lists callees of handler when body calls other fns; smoke: (callees "ui/nav") returns list; (callers "ui/menu") non-empty when nav calls menu; smoke: after redefine of a callee, impact-queue lists dependents + routes; smoke: agent install_function result text names impact routes to smoke; smoke: binding pages show recursion/tail classes and observability badges when function-observability ships*

==========
SHIPPED (v1 inspector) ==========
- binding AST pretty+JSON; data row JSON pretty - Function observability (lisp-interpreter.function-observability): recursion/tail HTML classes, step/DB stats, big-O badge, on-demand (analyze 'fn) / POST /api/analyze/:name, peel. - GET /page/<path>: routing panel + STATIC callee graph (App heads that are Vars ? visible function_defs; depth cap 8; cycles skipped) - /bindings "used by": DIRECT handler?route only (not full transitive reverse graph – perf; deep graph stays on /page inspect). Implementation note 2026-07: used_by_pages_map is handler-only to avoid N*depth PG lookups on every /bindings load.

==========
CHANGE IMPACT (planned) – reverse deps ? test obligations ==========
Motivation (language + OS): Live define/install is not proof the habitat still works. We already pay for a static call graph on inspect. Use it like Smalltalk senders + Nx "affected": when F changes, flag who depends on F and which routes to re-smoke.

Industry analogues (do not overbuild): IDE Find References, Bazel/Nx affected, Smalltalk senders, coverage-guided test selection. We want the live-image version, not a full CI product.

———- A. STATIC GRAPH API (shared kernel) ———- Reuse collect_var_apps / page_function_graph style analysis.

Forward (already): callees(name) ? user functions F statically calls (direct App Var heads that resolve to function_defs; optional ~depth default 1 for prims, 8 for inspect)

Reverse (NEW – function?function, not only routes): Build once per request or cache short-TTL on branch: for each visible binding B with body expr: for each direct callee C in collect_var_apps(body): callers[C] := callers[C] ? {B} callers(name) ? list of B that directly App-call name dependents(name, ~depth) ? BFS reverse edges, cap depth (default 8), cycle-safe; exclude name itself

Routes (extend used_by): used_by_routes(name): - always include routes whose handler = name - PLUS routes whose handler's transitive callees include name (reuse page_function_graph or reverse map from cached forward graphs). Cap cost: compute reverse route index when building callers map once per branch snapshot, not per /bindings row naively.

Nopales prims (session-aware, read-only, any authed user): (callees name [depth]) ? VList of VStr names (callers name) ? VList of VStr names (direct) (dependents name [depth]) ? VList of VStr names (used-by-routes name) ? VList of route path strings

Missing name ? () or empty list (not error). Prims/kernel names: callers may be empty; still OK. IMPORTANT (image.dnu-stubs): callers(name) MUST work when name is not yet a function_def – reverse index is built from all visible bodies' App-Var heads, not only defined callees. holes(name) lives in dnu-stubs; shares walk.

———- B. IMPACT QUEUE (on define / install) ———- When a binding is successfully defined or install_function succeeds for NAME on the current branch:

impact = { name: NAME at: timestamp branch: current branch ref author: whoami dependents: dependents(NAME) routes: used-by-routes(NAME) status: pending | smoked | dismissed }

Storage (v1): Session-local ring buffer (last N=32 impacts) on Session.t is enough for agent + UI banner. Optional later: data_rows type impact-event for cross-request durability.

Surfaces: 1) Nopales: (impact-queue) ? list of impact dicts/JSON strings (impact-clear [name|all]) (impact-mark name 'smoked|'dismissed) 2) define / install_function return path (agent tools): append human-readable block: "im-

pact: dependents=?; smoke routes: /a /b" If routes empty: "impact: no routes; eval dependents or smoke parents manually" 3) UI (light): /bindings or /edit/<name>: badge "N dependents" + link to impact panel; optional site chrome banner when queue has pending items for this branch (do not block editing).

Do NOT fail define because dependents exist – only notify.

———————————————- C. "NEEDS TESTING" LADDER ———————————————- L0 (MVP – ship first): awareness only (queue + agent text) L1: optional auto eval of pure dependents (if effect pure) L2: recommend/auto smoke_route for each used-by-routes entry (agent definition-of-done already requires smoke; impact tells WHICH paths) L3 (later): hard badge red until smoke or dismiss

Default ship L0+L2-hints. No blocking L3 in v1.

———————————————- D. AGENT SEED ———————————————- After install_function / eval define of a package function: - Read impact (tool result or (impact-queue)) - smoke_route every listed route (GET, contains marker) - eval_expr key pure dependents if no routes - Final summary must mention impact smokes

———————————————- E. LIMITS (honest static analysis) ———————————————- - No dynamic apply / computed names - Higher-order (map f xs) may miss f unless App head - Macros: graph is source App Vars (post-expand ideal later; v1 source walk matches today's inspector) - False negatives possible – route smokes remain truth - Noise control: only enqueue when NAME is a stored function_def (not every let-bound local); skip if dependents and routes both empty

———————————————- F. NON-GOALS ———————————————- - Runtime request traces / dynamic call sampling - Full CI product / GitHub integration - Coverage-guided line maps - Blocking save on dirty dependents - Cross-branch impact (only current branch visibility)

———————————————- G. IMPLEMENTATION PHASES ———————————————- Phase I1: shared graph helpers + (callees)/(callers)/ (dependents)/(used-by-routes); unit/smoke (callers works for missing names – DNU) Phase I2: impact-queue on define + install_function text; (impact-queue)/(impact-clear)/(impact-mark); same hook appends change-transcript (branching.change-set) Phase I3: /bindings detail Callers/Callees/Impact badge; agent seed paragraph Phase I4 (optional): short-TTL cache; L1 pure auto-eval

Combo-pack build order (whole five): I1 graph ? I2 define hooks (impact+changeset) ? browser detail panels ? dnu-stubs ? desktop 3-pane

———————————————- H. SUCCESS ———————————————- - Changing ui/menu shows ui/nav (or similar) in callers - used-by-routes for a shared helper lists real pages - Agent after install is told which routes to smoke - /bindings stays fast (no per-row depth-8 walk regress)

DEFERRED (still): eval-result inspect, type-def deep inspect, runtime traces, mutate-from-inspector.

========== COMBO-PACK NOTE ==========
Inspector owns graph + impact + value inspect (#1, #3). Browser hub: image.system-browser. Change transcript: branching.change-set. Holes: image.dnu-stubs. Define hook is the shared write path for impact + change-set append.

dnu-stubs

doesNotUnderstand-style holes: unbound names ? stub + callers for agents

[status: implemented]

– *agent note:* 2026-08-02: holes + stub-function prims; binding

page holes panel; unbound handler Create stub; session registers graph/DNU prims.

[verify] build: dune build image; smoke: eval unbound foo yields structured unbound_var with name=foo; smoke: (holes "ui/nav") lists App-Var names in body not bound as fn/prim; smoke: POST stub create missing name ? callable lambda TODO stub; smoke: unbound route handler page offers Create stub + Callers; smoke: agent after unbound error can stub then see callers of stub name

==========

WHY (Smalltalk doesNotUnderstand, agent-friendly) ==========

Live images fill holes instead of failing closed forever. Agents hit unbound names constantly (typos, planned fns, half-migrated packages). Today: bare Unbound_var / handler unbound cards. Goal: a closed loop without becoming CI:

missing name ? structured error (kind + name) ? who already calls it? (static callers – may be empty) ? one-click / one-tool stub (lambda TODO) ? edit + impact/smoke via existing inspector paths

This is NOT a full condition system (see lisp-interpreter.errors-and-locations for guard/catch). DNU here = product UX + agent affordance on holes.

==========

A. STRUCTURED UNBOUND (host) ==========

Keep raising Interp_error (Unbound_var name). Surfaces must expose machine fields (align with errors-and-locations C): kind: unbound_var name: <missing> source: optional define/handler context /api/eval JSON and agent tool errors include name= so agents do not regex the message. REPL print may stay one-line.

==========

B. STATIC HOLES IN A BODY ==========

holes(name) – for stored function NAME: walk body with collect_var_apps (same as graph) candidate = App-Var heads hole if not in: prim registry ? visible function_defs ? special forms ? lambda params / lets (best-effort; App heads only; accept false negatives on dynamic names) Nopales: (holes name) ? VList of VStr UI: browser detail + editor show Holes list.

==========

C. STUB CREATE ==========

Default stub body (same spirit as function-editor missing): (lambda () "TODO: implement <name>") Zero-arg v1; agent/human edits signature. Never invent args.

Paths: 1) function-editor missing card [Create] – already specified; dnu-stubs REUSES it (POST /api/edit/create) 2) Nopales (stub-function name) ? define stub if missing; error if already bound (use install/edit to overwrite) 3) Unbound handler HTTP response: card with handler H unbound [Create stub H] [Edit if exists] [Callers of H] 4) Agent tool optional stub_function name= – thin wrap over same define_binding; seed text: on unbound_var, stub ? install real body ? smoke impact routes

Creating a stub is a normal define: fires impact-queue + change-set transcript hooks.

==========

D. CALLERS OF A HOLE ==========

Even when NAME is unbound, reverse graph still finds B whose body App-calls NAME (static). (callers name) must work for missing names (build from all visible bodies), not only defined callees. Critical for "who wanted this?"

==========

E. NON-GOALS ==========

- Runtime doesNotUnderstand method dispatch / prototype OO - Auto-generating real implementations via LLM on every miss - Catching unbound inside every page without guard (that's errors-and-locations phase 2) - Stubbing kernel prim names

==========
F. PHASES ==========
D1: structured unbound name in /api/eval + (holes) D2: callers works for missing names; UI holes on detail D3: stub-function + unbound handler card + agent note D4: wire browser detail Holes panel (system-browser)

SUCCESS: agent sees unbound: foo with name field, stubs foo, finds callers, fills body, impact lists routes.

16 borge/multipart.borg

pricklypear-multipart

Pricklypear book chapter: multipart streaming responses
[status: implemented]

multipart

multipart/mixed streaming responses: one HTTP response, many independently-targeted htmx swaps. The reactive substrate.

mime-framing

One route response streams N MIME parts; each part is one htmx swap
[status: implemented]

> *[verify] build: dune build image; test: part / json-part / multipart prims build tagged values; test: keyword :target self-evaluates; smoke: route returns (multipart (part "one") (part "two")) => Content-Type: multipart/mixed; both parts present in body; smoke: peer disconnect mid-stream is a non-event (http-robustness invariant 1 holds on this path too)*

Inspired by scriptogre/multipart-response (Python adapters for Django/FastAPI/Starlette/FastHTML) and the htmx hx-multipart extension. Strip away the framework adapters and the idea is small: the server responds Content-Type: multipart/mixed; boundary=B and writes parts as they are ready. Each part carries its own headers – HX-Target / HX-Swap / HX-Part-ID – so every part is an independently-targeted htmx swap. One HTTP response becomes a stream of targeted DOM updates; no websockets, no SSE endpoint, no per-swap round trip.

NOPALES SURFACE (new prims, VStr-tagged like render-html): (part html) ; one part, text/html (part html :target "#feed" :swap "beforeend" :id "42") (json-part json-string :id "result") ; application/json part (multipart p1 p2 ...) ; list of parts (multipart :target "#feed" :swap "beforeend" p1 p2 ...) ; leading kwargs = envelope defaults for every part; ; per-part headers override envelope defaults.

ENVELOPE: Content-Type: multipart/mixed; boundary=<random> Envelope HX-Target / HX-Swap written as response headers (hx-multipart honors them as part defaults).

PART WIRE FORMAT (RFC 2046, minimal): –B\r\nContent-Type: text/html; charset=utf-8\r\n HX-Target: #feed\r\nHX-Part-ID: 42\r\n\r\n<body>\r\n ? final –B–\r\n. Bodies are checked for boundary collisions (on collision, regenerate boundary once, then raise User_error – do not silently corrupt).

RENDER PATH: respond_handler_value gains a branch: a multipart-tagged value sets multipart Content-Type and streams parts through the existing Httpun.Body.Writer (write_string + flush per part). The closed-writer guard and peer-gone invariants from image.http-robustness apply unchanged – a disconnect mid-stream MUST NOT take the process down.

v1 IS EAGER: the handler returns a fully-evaluated list of parts; the kernel frames and streams them. You get multiple targeted swaps in one response – the reactive payoff – without lazy generators in the interpreter. Deferred: Nopales-level streaming sources (generator or (multipart-stream (lambda (emit) ?)) callback style) and HX-Last-Part-ID resume for live tails.

hx-multipart-vendored

Vendor htmx hx-multipart extension; static asset, no CDN dependency
[status: implemented]

[verify] build: dune build image; smoke: GET /assets/hx-multipart.js returns 200 with the extension source

The client half is the hx-multipart htmx extension (four.htmx.org/extensions/hx-multipart), which parses the multipart stream via fetch-multipart and performs one swap per part, honoring per-part HX-Target / HX-Swap / HX-Select and the HX-Part-ID / HX-Last-Part-ID reconnect cursor.

Vendored next to the CodeMirror assets (/assets/cm/*) so the image works without a CDN. Pages opt in with hx-ext "hx-multipart" on the triggering element.

repl-v2

Advanced browser REPL: one input, streamed multipart output – LLM answers, slash commands, live eval

[status: implemented]

[verify] build: dune build image; smoke: (+ 20 22) as input => 42 multipart part; smoke: /note hello there => confirmation part appended; smoke: error in eval => error part styled distinctly; smoke: /branch => whoami @ branch part; smoke: GET /assets/hx-multipart.js 200

The advanced REPL is a Nopales package (libs/repl) built on the multipart substrate – the dogfood that proves it. One interface, one input box, and the response is a multipart stream whose parts append to a scrolling transcript.

INPUT DISPATCH (repl/answer): - "/cmd args?" -> slash command (dispatch table, see below) - "(?" -> Nopales eval via the same Session.eval_one path as browser-repl / /api/eval – NOT a second interpreter - otherwise -> LLM question via libs/ai (ai/ask-shaped: agent-session + context block)

A single submission can yield SEVERAL parts – that is the point. An LLM question streams its deltas as parts (llm_client already supports stream:true with on_event callbacks); an eval can yield a "running?" part, then the value part, then a notes-link part. Each part targets the transcript (HX-Target #transcript, HX-Swap beforeend) or replaces a placeholder part by id.

SLASH COMMANDS (v1): /note <text> capture into notes (dailies-and-capture path) /eval <expr> explicit eval (same as bare "(" input) /describe <pkg> package surface summary part /branch current branch + whoami part /help command list part Commands are functions in the package; users add their own with (repl/command "todo" 'my/handler).

IDENTITY: runs on the caller's branch with the caller's session (route is private by default). LLM key resolution follows auth.user-llm-keys (personal key, operator fallback).

RELATIONSHIP TO EXISTING SURFACES: browser-repl stays – the simple /repl + POST /api/eval path is the low-level tool (and the agent API). repl-v2 is the human cockpit: LLM + commands + eval in one streamed transcript. If it earns its place, /repl can later point at it; that decision is NOT part of this section.

live-streaming

Token-level streaming: LLM deltas and long-running evals appear incrementally in the transcript, not as one final part

[status: planned]

[verify] build: dune build image; smoke: LLM question in repl-v2: first token appears in <1s, subsequent tokens append live, final part completes the bubble; smoke: eval that yields multiple values streams each as it completes, not batched at end; smoke: error mid-stream yields error part and closes response cleanly; smoke: peer disconnect mid-stream is a non-event (http-robustness invariant 1)

RECONCILE (BORGE-1786263466): LLM live-streaming is SHIPPED via a DEDICATED OCaml route – /repl-v2/llm (repl_llm in image/lib/http_agent.ml) – which reuses the proven /api/agent SSE queue/drain pattern, NOT the general Nopales (multipart-stream (lambda (emit) ...)) mechanism spec'd below. Rationale (recorded choice): the /api/agent SSE queue/drain is battle-tested and lower risk; calling Nopales emit callbacks from OCaml on_event fibers needs effects/run_lwt coordination that cannot be runtime-verified without a live LLM in one session. Eval/slash stay on the Nopales /repl-v2/send route (eager); LLM input is routed client-side to /repl-v2/llm via an htmx configRequest hook. The GENERAL (multipart-stream ...) mechanism below remains FUTURE WORK – this stanza stays planned but must describe reality until then.

(The shipped shape below is the still-planned general mechanism, superseded for LLM streaming by /repl-v2/llm.) Current repl-v2 is EAGER: the handler computes all parts, then multipart frames them. For LLM answers this means the user waits for the full completion before seeing anything. The fix is live streaming: the handler yields parts as they are ready, and the kernel flushes each part over the wire immediately.

KERNEL CHANGE: respond_handler_value gains a streaming branch. Instead of evaluating to a list of parts then framing, the handler runs with an emit callback: (multipart-stream (lambda (emit) (emit part1) (emit part2) ?)) Each emit writes one MIME part and flushes. The existing Httpun.Body.Writer write_string + flush per part becomes the streaming path.

NOPALES SURFACE: (multipart-stream (lambda (emit) ?)) emit is a function of one argument (a part value). The lambda body runs to completion; each emit call pushes a part to the client. Errors inside the lambda emit an error part and close the stream cleanly.

AI INTEGRATION: libs/ai/ai/ask gains a streaming variant (ai/ask-stream on-event) where on-event receives deltas. repl-v2's LLM branch uses it: each delta emits a part targeted at the transcript, building up the answer token by token. The final delta emits a completion part that styles the bubble as done.

SCOPE: only LLM streaming in repl-v2 v1. Eval streaming (multiple values over time) is a follow-up. The prim name collision bug (BORGE-1786262466: agent-session-new vs Agent_tools.agent-session-new) must be fixed first – the LLM path is broken without it.

repl-v2-ux

REPL transcript polish: echo user input, clear form on send, distinct styling per message kind

[status: implemented]

> *[verify] build: dune build image; smoke: user input appears in transcript before response; smoke: form input clears on successful send; smoke: form input clears on error send (no stuck text); smoke: error parts styled distinctly from value/llm parts*

All three UX gaps closed across BOTH input paths – the Nopales /repl-v2/send route (slash commands + eval) and the OCaml /repl-v2/llm route (plain-text LLM input, routed client-side by an htmx configRequest hook).

1. USER ECHO: repl/send (libs/repl/lib.pp) prepends repl/user-echo – one user bubble part (raw input, .repl-user class, italic) before the response parts. The OCaml /repl-v2/llm route (image/lib/http_agent.ml repl_llm) emits the same user-echo bubble as its Part 1, so the transcript reads two-sided on both paths.

2. FORM CLEAR: the repl-form clears on hx-on::before-request (immediate, on submit) AND hx-on::after-request (fallback reset) so no input is ever left stuck – the before-request hook avoids the after-request race with the swap and also clears the box while a long LLM stream is still running.

3. STYLING: each message kind gets its own border/paint via the repl-line base + per-kind classes (.repl-value/.repl-error/.repl-llm/.repl-note/.repl-user); the LLM failure case emits a .repl-error span with a human-readable message ("error: ?") instead of a raw exception string, and error parts carry a red border + pink background distinct from value/llm parts.

(The user-echo work is what makes the transcript readable – without it the transcript reads one-sided and the user loses track of what they asked.)

17 borge/hypermedia-harness.borg

pricklypear-hypermedia-harness

Pricklypear book chapter: a headless hypermedia client – a server-side htmx swap simulator that is the reference implementation of the fixi-five contract, for debug agents and verification harnesses. It runs in the image, fetches no HTTP, runs no browser, and calls route handlers in-process.

[status: implemented]

> – *agent note:* 2026-08-14 RECONCILE, with agent.borg: the harness is now a SHARED, host-portable layer. soup/* stays DB-free and is lifted into the shared pure-prims layer so the image (Postgres corpus) and the agent (local-first lens corpus) register the same tree prims. The ONE host seam is route/dispatch + route/lookup (request-runner): Nopales signatures identical, host-local backing (Session.t Postgres routes vs Runtime.t lens routes; fat Request_context vs thin agent request context). libs/hyper runs unchanged on both. Streaming swaps (hx-multipart multipart/mixed, HX-Target/HX-Swap per part) move INTO the contract as data – soup/apply-parts! applies an ordered part list; hyper/stream wraps it immutably; transport/timing stays CDP-tier (unsupported-boundary). This is the refactor that lifts the agent's chat/agent UI from SSE+vanilla-JS to Nopales-authored htmx fragments.

hypermedia-harness

A headless htmx client living inside the image. It invokes route handlers in-process, parses the returned HTML into a tree, and applies htmx swaps (target + strategy + out-of-band) to that tree – the exact state machine of the production browser client, restricted to the fixi-five subset. Debug agents use it as a cheap, deterministic verifier; the authenticated, no-browser surface is callable through /api/eval with no new REST surface.

contract

The executable contract is the fixi-five intersection: the semantic core shared by htmx (the production client) and fixi (the minimal reference) – fetch + swap, five attributes (get/post/target/swap/ trigger). The harness is the reference implementation for this subset; within it, the harness is authority and the production client (htmx 4) must conform. Outside it, htmx 4 is authority and the harness declines. The contract is the shared object of which fixi is the most compact correct statement; it does not move when the production client changes.

[status: implemented]

supported-subset

Attributes the harness models, mirroring htmx 4 semantics under the htmx-2-compat defaults PP ships.

MODELED: - hx-get, hx-post, hx-target, hx-swap, hx-trigger – the fixi five - Inherited hx-target / hx-swap / hx-confirm via ancestor lookup (mirrors the implicit-inheritance mode restored by htmx-2-compat) - hx-swap-oob: main content swaps FIRST, then OOB elements swap after (htmx 4 ordering; OOB elements are hoisted from anywhere in the response, including nested within the main target) - hx-confirm: proceeds without the consent gate (a UI affordance, not behavior) - hx-vals: JSON values only - Swap strategies: innerHTML, outerHTML, beforebegin, afterbegin, beforeend, afterend, delete, none

- hx-multipart streaming swap class: a multi-part streamed response (multipart/mixed, one fragment per part, each with per-part HX-Target/HX-Swap headers – see kernel-prims apply-parts!) is modeled by applying the captured part list in order onto the page (soup/apply-parts!), not by racing bytes over a socket. The stream is reduced to data before the harness consumes it, so the swap semantics are the same fixi-five swap machinery applied N times, deterministically.

[status: implemented]

unsupported-boundary

Features the harness returns unsupported-feature for, instead of modeling. These flows graduate to the CDP/browser verification tier rather than being silently under-modeled.

NOT MODELED (returns unsupported-feature): - hx-on scripting – client JavaScript; opaque without a JS engine (the moxi.js boundary; the harness may record that a script existed but cannot execute it) - hx-push-url – history; no fixi equivalent - hx-ext – inert in htmx 4 (extensions activate by script inclusion) - hx-vals with js: prefix – cannot eval JS - Triggers with debounce / throttle / delay modifiers - hx-sync – request queueing and coordination - hx-boost, hx-ws – not used in PP's markup; out of scope. - hx-sse transport/timing – the streaming SWAP class is now MODELED (supported-subset hx-multipart: an ordered part list applied via soup/apply-parts!). What stays NOT MODELED is the transport/timing axis – racing bytes, reconnect, server push cadence – which is not a swap semantic and graduates to CDP. The absence of hx-boost/hx-ws from PP's markup is why the fixi-five subset is a faithful contract for PP, and the trigger to revisit this boundary is concrete: the day either appears in libs/, the subset must either grow or that flow must acknowledge the CDP tier.

[status: implemented]

kernel-prims

Thin lambdasoup bindings – the HTML tree layer. lambdasoup and markup are already in the poohstack opam switch; no new dependency. Prims are registered under the soup/ namespace (not html/) to avoid colliding with the pure-html DSL prims (html/attr, html/text, html/div, ...) that page rendering depends on.

PRIMS (uppercase, DB-free, part of the pure-prim layer, soup/ namespace): (soup/parse str) -> page handle (soup node) (soup/page-copy page) -> new page handle (deep copy; immutability: source never mutated) (soup/select page selector) -> list of node handles (soup/select-one page selector) -> node handle | nil (soup/serialize page|node) -> HTML string (soup/text page|node) -> concatenated text content (soup/attr node name) -> string | nil (soup/has-attr node name) -> "true" | nil (soup/swap! node style fragment) -> mutate in place (style = one of innerHTML, outerHTML, beforebegin, afterbegin, beforeend, afterend, delete, none) (soup/create tag) -> node handle (soup/replace node fragment) -> replace target with fragment's nodes (soup/closest-attr node name) -> ancestor walk for inherited hx-target/hx-swap/hx-post resolution (mirrors htmx compat implicit inheritance) (soup/parent node) -> node handle | nil (soup/diff a b) -> structured what-changed report (added/removed ids + text changes within same-id elements) (soup/apply-parts! page parts) -> mutate in place; parts is a VList of part alists, each (("html" . frag) ("target" . sel) ("swap" . strat)); each part is located (soup/select target) then swapped (soup/swap! strat frag) in ORDER. target/swap absent -> caller's element + "innerHTML", matching hyper/do-swap defaults. Matches the multipart/mixed wire shape http_agent.mp_write_part emits (per-part HX-Target/HX-Swap); see supported-subset hx-multipart.

Mutations use lambdasoup's append_child / insert_before / insert_after / delete / clear / set_attribute. The diff is node-level (which ids changed, added, removed, or text-changed), not a raw text diff – this is the agent-facing value: a compact report instead of dumping DOM into model context.

SHARED KERNEL. The soup/ tree layer is DB-free. It is lifted out of image/lib/prims_hyper.ml into the shared pure-prims layer (pure/, alongside prims_pure.ml) so BOTH hosts register the same prims: the image (Postgres corpus) and the agent (local-first lens corpus). Only route/dispatch + route/lookup + the request-runner remain host-specific (they touch the host's store / routes / request context – see request-runner). lambdasoup + markup become deps of the agent package, joined on the same seam.

[status: verified]

> *[verify] build: dune build image; test: soup/parse + soup/select round-trips a server-rendered /notes page; test: soup/swap! applies each of the eight strategies correctly; test: soup/diff detects added, removed, and changed nodes; test: soup/apply-parts! applies an ordered part list into the page: each part's fragment lands at its target with its swap strategy, in sequence*

request-runner

In-process dispatch reuses existing machinery – no new transport. The harness binds a synthetic request and invokes a routed handler the same way the HTTP gate does, without an Httpun socket. This is THE HOST SEAM: the only prims that differ between hosts. The image backs them with its Postgres corpus (Session.t routes + store + Request_context manifest); the agent backs them with its local-first lens corpus (Runtime route table + a thinner request context). The Nopales signatures are identical, so libs/hyper runs unchanged on both hosts.

Request_context.make ~manifest ~env ~routes constructs the per-request snapshot (the image.per-request-context pattern from the http-robustness work). Session.call_handler session ~request handler_name invokes the routed handler with the synthetic request bound so request-prims (hx-request?, query-param, current-author) resolve correctly for the duration of the call. Returns Handler_ok v – the rendered value the browser would receive. No HTTP round-trip, no socket, no chromium.

NOPALES BRIDGE (new prim, session-capturing – same registration pattern as crud.ml: registered in session.ml via a register_* call that closes over the Session.t; the late-bound thunk in session.ml closes over call_handler to avoid a forward-reference): (route/dispatch handler-name method path [params] [headers] [body]) -> raw-HTML VStr Binds a per-call Request_context (with_current) so handler prims resolve, calls Session.call_handler, and returns the rendered value as a VStr (the same string the browser receives – is_raw_html-tagged values unwrap per render_handler_value). hyper/visit and hyper/click sit on top of route/dispatch. (route/lookup path) -> handler-name VStr | nil resolves a URL path to its handler via the route table.

AGENT HOST BACKING (see agent.borg agent-route-table). The agent implements the SAME prim signatures against its runtime: routes live on a Runtime-scoped route table (Runtime.t.routes), populated by the agent's (route path handler) prim reading its lens-resident defs; dispatch invokes the Nopales handler through Runtime.apply_value under the eval rim; the request context is THINNER (no Postgres manifest / branches / auth – only the request-shaped prims resolve: query-param, request-method, hx-request?). Request prims that need a DB/branch (e.g. current-author-as-DB-row) are unbound in the agent; the agent's request context provides only the request-shape values. This is the intended portability seam: same prims, host-local backing.

[status: verified]

[verify] build: dune build image; smoke: route/dispatch on a routed page handler with a synthetic GET context (Request_context bound) returns the same HTML the HTTP gate returns for the corresponding GET; smoke: agent: route/dispatch on an agent-registered handler runs the Nopales fn through the runtime and returns its rendered fragment (no Postgres)

nopales-surface

The client semantics, written in Nopales over the kernel prims and the request runner. Lives in a new package libs/hyper. Page is an immutable threaded value: each interaction returns a NEW tree (deep-copied via soup/page-copy before mutation), giving free time-travel history and a cheap what-changed diff.

SURFACE: (hyper/visit url) ; resolve via route/lookup, GET ; in-process (no HX-Request header, ; so handler returns the full page ; like a browser's initial nav), ; soup/parse body -> page value (hyper/click page sel params) ; resolve trigger at sel OR nearest ; ancestor (inherited hx-post/hx-get ; via soup/closest-attr), read ; hx-target/hx-swap (inherited), ; POST in-process with HX-Request, ; soup/page-copy the page, soup/swap!, ; return NEW page (hyper/text page sel) ; first match's text content (hyper/query page sel) ; list of node handles (hyper/count page sel) ; element count (hyper/html page) ; serialize tree -> string (hyper/attr node name) ; attribute value (hyper/diff p1 p2) ; node-level what-changed (hyper/expect page sel expected) ; assertion (for smokes) (hyper/stream page parts) ; apply an ordered multipart ; part list onto a page via ; soup/page-copy + soup/apply-parts!, ; return NEW page (immutable: ; input page unchanged). parts ; come from the host stream as ; DATA (agent: loop.ml collects ; the emitted HX-Target/HX-Swap ; parts; image: http_agent ; mp_write_part). Lets hyper/** ; assert a consumed chat/agent ; turn deterministically. (hyper/sandbox branch body) ; v1 stub – branch checkout with ; restore needs dynamic-wind

INVARIANTS: - Each interaction returns a new page value; the input page is never mutated in place (enables history and diff). - hyper/click on a node whose trigger falls outside the supported subset (e.g. data-ol-op toolbar buttons, which are client-JS driven not htmx) returns unsupported-feature rather than a best-guess swap. - hyper/sandbox (v1 stub) does not yet check out a branch.

[status: implemented]

[verify] build: dune build image; smoke: hyper/visit on a notes fixture returns a page whose ol-node count matches the server-rendered page; smoke: hyper/click on a button with hx-get=/welcome hx-target=#out swaps #out content; the original page is unchanged (immutability); smoke: hyper/click on a data-ol-op node (client-JS-driven, not htmx) returns unsupported-feature; smoke: hyper/expect on a selector raises on mismatch and returns true on match; smoke: hyper/diff between two pages reports the node that changed

fidelity-gate

The conformance lock between the harness and the production browser client. The same flow is driven twice – once through CDP against a live browser running htmx 4, once through hyper/* – and the resulting DOM text is asserted byte-identical. Divergence is either a harness bug (the simulator is wrong and must learn the quirk) or an htmx quirk the harness must mirror. Once a flow is green twice via CDP, it graduates to a hyper/ smoke that runs in milliseconds with no browser. The visit step is proven byte-identical; multi-step swap fidelity is deferred until a real hx-get/hx-post flow is targeted (the notes outline toolbar is JS-driven data-ol-op, not htmx, so it is correctly the unsupported-feature boundary, not a fidelity target).

[status: implemented]

[verify] build: dune build image; smoke: drive GET /notes?slug=ui-fixture via CDP and via hyper; assert byte-identical #outline DOM text at the visit step

18 borge/product-experience.borg

pricklypear-product-experience

Pricklypear book chapter: product-experience
[status: implemented]

> – *agent note:* 2026-08-02 status reconcile: concepts/access/vocab/first-run/public-release already impl; analytics+reliability matched to shipped ops_* modules; horizon design-only ? implemented. Live /analytics 200; ops/summary day rollup.

product-experience

Human-facing product layer: concepts, access paths, legible vocabulary, first-run, horizon
[status: implemented]

> *[verify] build: dune build image; smoke: GET /about teaches concepts; home offers first-run hello recipe; smoke: scripts/repl.sh logs into REPL*

Pricklypear is a multi-user live computing environment: log into your image, write Nopales functions stored as data, branch code while sharing data, bind functions to URLs, let AI propose functions onto a branch.

Product experience is the thin skin that makes the dense substrate legible. Without it, only authors understand the system.

LAYERING (aligned with image.system-browser + image.product-theme, 2026-07-12): - Environment UI humans live in (nav, home, app menus, theme/presentation, user routes) is Nopales on branches (libs/*.pp seed + personal pins). That is the product. - OCaml hosts Nopales: eval, store, auth gate, health, kernel system pages (/bindings, /edit, ?), and a labeled emergency shell if ui/nav, ui/home, or ui/css fails. - OCaml must not ship a silent second product nav/home or a silent full design-system CSS twin in http.ml. Dual silent defaults are rejected architecture. - Theme is Path B (honest Nopales): css/* sheets + tokens, not CSS-string-in-lambda as the native form.

concepts-guide

In-app about page: glossary, access, first tour, horizon summary
[status: implemented]

> *[verify] build: dune build image; smoke: GET /about contains Image, Store, Function, Branch, Route, AI*

GET /about (kernel OCaml page today; may move to Nopales later) MUST explain:

WHAT: multi-user live Nopales environment; image=CPU, Postgres=disk; Smalltalk tradition without OOP image dump.

GLOSSARY: - Image: running process (REPL + HTTP); single-image v1 - Store: Postgres durable truth - Function/binding: named live value; define persists - Branch: versioned code world; data shared - Type/row: deftype + data_rows CRUD - Route/page: URL bound to a function - Shell (ui/menu, ui/nav, ui/home, ui/theme, ui/css): Nopales product chrome + presentation - Theme tokens (theme/bg, ?): branch-visible style knobs - AI propose: agent authors on current branch only

ACCESS: - scripts/dev.sh start (PG + image) - Browser: /login (app session) then / /repl /edit /bindings - scripts/pp_eval.py or Basic auth for agents - scripts/repl.sh / line-protocol REPL when enabled - nginx basic-auth may sit at edge; not the user DB

FIRST TOUR: log in, define hi-page, route /hello, open page, edit ui/menu for navbar, optional propose-function.

Link from home nav and home body. Full horizon detail in product-experience.horizon.

access-paths

Documented ways humans reach a live image
[status: implemented]

> *[verify] smoke: GET /login form; POST /login mints pp_session; smoke: scripts/verify_auth.sh or auth_product_smoke passes; smoke: scripts/repl.sh connects when line-protocol enabled*

v1 SHIPPED paths (single-image): 1. Browser: GET/POST /login ? cookie pp_session ? land on username/personal; POST /logout revokes 2. Admin: /admin/users (create user, revoke sessions) 3. Agents: HTTP Basic or session cookie ? /api/eval (scripts/pp_eval.py) 4. scripts/dev.sh start – PG + image 5. scripts/verify_auth.sh product gate 6. Optional scripts/repl.sh / line-protocol REPL

Product chrome after login is Nopales (ui/nav, ui/home, ui/theme/ui/css). Auth gate and emergency shell/CSS are OCaml kernel only.

MULTI-USER ACCESS (planned – auth.* subsections): - Per-user subdomain: https://{user}.{PP_BASE_DOMAIN}/ (auth.user-subdomains); apex login redirects home - Per-user LLM key: credentials llm_key; /settings/keys (auth.user-llm-keys); env LLM_API_KEY is fallback only - SSH ? REPL: credentials ssh_key; PP_SSH_PORT opt-in or OpenBSD sshd bridge (auth.user-ssh-repl)

MULTI-USER SOCIAL (planned – multi-user.*): - Chat lobby + DMs: /chat, (chat/say ?) (multi-user.chat) - Unix .plan: /plan, /u/:user, (plan "?") (multi-user.user-plan)

DEFERRED: - Fleet boot/attach per user (process isolation path) - Custom domains per user - Drop nginx htpasswd as primary human gate (break-glass only; already not the user DB)

vocabulary

Friendly UI labels over systems jargon
[status: implemented]

> *[verify] smoke: nav/home use Functions (not only Bindings) and point to /about*

UI vocabulary (human): Functions <- function_defs / bindings Pages <- view_bindings / routes Data <- type_defs + data_rows Workspace <- current branch + whoami About <- concepts guide

HARD RULE: Page ? Function. Page = URL endpoint (/hello). Function = named code (hi-page). Edit targets are always function names (/edit/hi-page). Page inspect is /page/hello (route + call graph). Never nav-link /edit/<route-basename> as if it were a function.

PACKAGE vs BRANCH: Package = in-branch prefix (todo/) for organizing functions. Branch = versioned workspace (system/main). UI labels: "package" for prefixes, "branch"/"workspace" for version worlds – never swap the words. Functions browser groups by package; branch chrome stays whoami + current branch.

Nopales/REPL vocabulary stays technical (define, route, deftype, rows). The browser skin translates.

first-run-recipe

One-click or one-form 'make a hello page' onboarding
[status: implemented]

> *[verify] build: dune build image; smoke: POST /api/recipe/hello creates hi-page route; GET /hello works*

Recipe "hello page": 1. Define function hi-page -> render-html greeting 2. (route "/hello" "hi-page") 3. Return link to /hello and /edit/hi-page
Exposed as: - Button/form on home - POST /api/recipe/hello
Non-goals: full app wizard (that's AI app-sketch later).

public-release

Hosted public face on the image: layout components, welcome, code browser, book PDF, source tarball
[status: implemented]

> *[verify] build: dune build image; smoke: unauth GET /welcome returns 200 with hero; smoke: unauth GET /code returns tree + codemirror shell; smoke: unauth GET /code/raw/pricklypear.borg returns text; smoke: unauth GET /book.pdf or 404 if artifact missing; smoke: unauth GET /src.tgz or 404 if artifact missing; smoke: path escape /code/raw/../etc/passwd denied; smoke: unauth GET /bindings still redirects to login; smoke: unauth GET /.well-known/agent.json returns 200 application/json with auth+eval contract; smoke: unauth GET /agent.txt returns 200 text/plain agent instructions; smoke: unauth GET /agent still denied (private portal); smoke: unauth POST /api/eval still denied*

========== GOAL ==========
Release pricklypear on the hosted instance itself – not GitHub-as-homepage, not a sister brochure site. The live image IS the public site:

/welcome – landing (Nopales layout/* + welcome/page) /code – read-only source browser (kernel + CM5) /book.pdf – borge book print artifact /src.tgz – pruned source tarball /.well-known/agent.json – machine agent bootstrap /agent.txt – prose agent instructions (auth + eval) /login – enter the private workspace

NOTE: /agent is the PRIVATE in-image agent portal (HTML), not the public discovery doc. Public agent onboarding is /.well-known/agent.json + /agent.txt only.

/book (HTML explainer) is NOT public-facing – PDF + /code cover the literate book story. Any welcome/book page is private workspace chrome only, not a front-door path.

Workspace home (/) stays HARD PRIVATE. Anon hitting / redirects to /welcome (or login with next=); logged-in users keep product home (ui/home).

========== LAYOUT COMPONENTS (libs/layout) ==========
Namespace layout/* – NOT public/*. "public" is reserved for route visibility / gate language.

Building blocks (pure HTML strings via html/*): layout/hero title tagline actions-html layout/card title body layout/cards list-of-card-html layout/section title body layout/cta href label layout/theme – css/sheet rules for .layout-*

Seeded on system/main; used by welcome (and private) pages. Personal gardens may override layout/* like any package.

========== WELCOME PAGE (libs/welcome) ==========
welcome/page – compose layout/* into landing (public-route "/welcome" "welcome/page")

welcome/book may exist as a private helper, but MUST NOT be registered public and MUST NOT be a SYSTEM_HARD_PUBLIC path. Reseed should (route "/book" ? 'private) or drop the binding so older public /book rows flip closed on deploy.

Also register hard-public kernel paths so the front door works even if seed/route table is empty (belt + suspenders): /welcome is hard-public and dispatches to Nopales when bound, else a minimal kernel fallback page.

CTAs: Explore source ? /code ; Download book ? /book.pdf ; Source tarball ? /src.tgz ; Log in ? /login.

==========

CODE BROWSER (kernel, image/lib/http_code.ml) ==========

Read-only filesystem browser over PP_SOURCE_ROOT (default: repo root / PP_ROOT / cwd with libs+image+lisp).

Routes (all hard-public GET): /code – HTML shell: file tree + CodeMirror /code?f=path – open file in editor /code/raw/<path> – raw text (for fetch into CM) /assets/cm/* – vendored CodeMirror 5 assets

CodeMirror 5 (vendored, no npm at runtime): codemirror.min.js + codemirror.min.css mode/mllike (text/x-ocaml for .ml/.mli) mode/markdown for .md plain for .borg .pp .sql .sh readOnly: true, lineNumbers: true

SANDBOX: - realpath must stay under PP_SOURCE_ROOT - allowlist extensions: .borg .ml .mli .pp .md .sql .sh .ksh .dune (and dune files named "dune") - skip dirs: _build .git .pi .ralph node_modules _opam .opamswitch spikes (optional) supervisor (deprecated – skip) image/static/codemirror is ok - max file size ~2 MiB - GET only; no write/eval

Default open file: pricklypear.borg when present.

==========

BOOK PDF + TARBALL ==========

Built at deploy/dev time, not per-request:

borge book print . -o pricklypear-book scripts/public_artifacts.sh ? PP_PUBLIC_DIR/book.pdf (or pricklypear-book.pdf) src.tgz (same allowlist as /code)

Image serves: GET /book.pdf application/pdf GET /src.tgz application/gzip from PP_PUBLIC_DIR (default /tmp/pp-public or beside source). Missing artifact ? 404 with short HTML hint, not crash.

==========

AUTH GATE EXTENSIONS ==========

SYSTEM_HARD_PUBLIC gains: /welcome /book.pdf /src.tgz /code and /code/* /assets and /assets/* /.well-known/agent.json /agent.txt (/book is NOT hard-public) (/agent is NOT hard-public – private portal)

Still HARD PRIVATE: / /bindings /edit /repl /data /api /admin /branches /types /pages /agent ?

==========

AGENT DISCOVERY (public bootstrap, no secrets) ==========

Remote agents (Agora, pi, curl on a phone) need a front door that explains how to talk to the image WITHOUT a checked-out repo. Ship two hard-public kernel GETs:

GET /.well-known/agent.json Content-Type: application/json Machine contract: name, version, philosophy, auth scheme (HTTP Basic / session cookie), eval endpoint (POST /api/eval request+response shapes), bootstrap first_calls, rules, curl/python examples, related public links. NEVER include passwords or tokens.

GET /agent.txt Content-Type: text/plain; charset=utf-8 Same content as prose Markdown/plain instructions a freeform agent can ingest wholesale.

Implementation: kernel handlers in image/lib (stable contract), not Nopales routes – discovery must work even when seed/route table is empty. base_url may be derived from Host / X-Forwarded-* when present, else omitted or a relative-friendly note.

Eval stays hard-private: unauth POST /api/eval ? 401. Agents supply image credentials (same as /login).

Anon / ? redirect /welcome (product choice for public host). Logged-in / ? ui/home as today.

========== ENV ========== PP_SOURCE_ROOT – tree for /code and tarball input PP_PUBLIC_DIR – book.pdf + src.tgz PP_LIBS_DIR – existing; layout+welcome seed from here

analytics

Product metrics page: viewers, logins, traffic – observation not work

[status: implemented]

– *agent note:* 2026-08-02: ops_stats + http_ops /analytics + ops/summary prim. Live day rollup; GET /analytics 200.

[verify] build: dune build image; smoke: GET /analytics (authed) shows day rollup: viewers, page views, logins; smoke: (ops/summary) returns structured day stats via /api/eval; smoke: public /welcome increments viewer/page counters; /assets/ excluded; smoke: login success/fail counts match auth_log for the day*

PURPOSE A habitat-native analytics page – not Datadog. Answers: "who showed up, what did they hit, how many logins?" Reliability *counts* appear here; reliability *work* lives in notes/todos (see reliability-work-queue).

SPLIT (product law) - /analytics = observatory (numbers, trends) - notes/todos = workshop (errors become fix work) Never dump raw log lines into the analytics page as the primary UX. Link out to open incident todos.

EMIT (request edge, one place in HTTP middleware) After identity resolve, for each request record: day, path_class, method, is_authed, status_bucket, viewer_key = hash of (client_ip + day salt) – no raw IP in the UI. Exclude /assets/*, /health, static bots path classes (wp-admin, .env probes) from uniques or bucket as "noise". Prefer in-memory day counters flushed periodically; do NOT insert one Postgres row per public request.

AUTH NUMBERS Source of truth: existing auth_log (password/mint ok|fail). Daily login_ok / login_fail via SQL count, not a second write path on POST /login.

ROLLUP SHAPE (v1) In-process Ops_stats for "today" + optional data_rows type ops-daily for prior days (fields JSON): day, unique_viewers, page_views, logins_ok, logins_fail, authed_requests, errors, fatals, top_paths (list). Counters flush periodically (in-memory day counters plus optional ops-daily rows); there are NO per-request Postgres inserts.

SURFACE - GET /analytics (hard-private; any logged-in user in v1, admin-only later if multi-tenant sharpens) - Nopales (ops/summary [day]) (ops/top-paths [n]) - Agent tool ops_summary (read-only) - Nav: link from ui/nav under system/admin cluster when package ops is seeded (or kernel chrome link)

UNIQUE VIEWERS (honest labels) - public_uniques: distinct viewer_key on hard-public paths - logins: successful auth_log password/mint that day - active_users: distinct authed usernames that day Do not conflate the three in the UI copy.

NON-GOALS v1 Session replay, heatmaps, off-box export, per-hit PG inserts, GA-style retention cohorts.

reliability-work-queue

Structured errors ? fingerprint ? note + todo; LLM enriches work items

[status: implemented]

– *agent note:* 2026-08-02: ops_log + ops_incidents fingerprint?note/todo; log-tail + ops/incidents. LLM enrich optional later.

[verify] build: dune build image; smoke: (log-tail 20) returns recent structured events; smoke: Error-level log creates/upserts one open incident fingerprint; smoke: repeat same error bumps count, does not create duplicate todo; smoke: incident filing creates a note body + open todo-item; smoke: optional LLM enrich rewrites title/body without changing counts

PURPOSE Errors should become work. The habitat already is notes + todos; reliability must enter that queue, not only sit on an ops dashboard. Analytics shows counts; this subsection turns severe/new failures into fixable garden items.

STRUCTURED LOG (primary stream) Ops_log ring in the image process: {ts, level, component, msg, context alist, fingerprint} Levels: info | warn | error | fatal. Always mirror to stderr (/var/log/pricklypear/image.log) for operator crash forensics. Bounded ring (e.g. 5k). Closed-writer / handler / seed failures go through Log, not bare Printf.eprintf forever (migrate hot sites).

FINGERPRINT key = component + "|" + normalized msg head (strip UUIDs, paths ids). One open incident per key. Upsert: count++, last_seen, sample_msg, sample_context. New key OR fatal OR watchdog restart ? file work item. Bot 404 noise stays analytics-only (warn or ignored).

WORK ITEM SHAPE 1. data_rows type ops-incident (machine state): fingerprint, level, component, count, first_seen, last_seen, status (open|resolved), note_slug, todo_id, sample_msg 2. notes: durable human/agent readable writeup slug ops-incident-<shortfp> or capture under inbox 3. todo-item: open TODO linked in notes field to the note Dedup rule: if open ops-incident exists for fingerprint, bump counts only – do not mint a second todo.

LLM ROLE (enrichment, not detection) Detection = fingerprints + thresholds (deterministic). LLM optional pass: input = fingerprint + samples + counts + recent log-tail output = better title, explanation, suggested fix/repro Write into the note body / todo title. Never invent counts. If LLM down: still file terse template note+todo. Trigger: on new incident, or admin "Enrich" / hourly batch for open incidents lacking ai_enriched flag.

CLOSE THE LOOP status ? resolved when: - todo marked DONE, or - no matching error for N hours (optional auto), - admin resolves on /analytics Resolved incidents do not re-open on single blip; require count threshold or fatal to reopen.

PRIMS / AGENT (log-tail n [level]) (ops/incidents [status]) (ops/file-incident ...) ; mostly internal Agent tools: read_logs, ops_summary, list_incidents (read); write tools stay effect-gated as today.

WATCHDOG OpenBSD cron watchdog remains the process safety net (scripts/openbsd/pricklypear-watchdog.ksh). On restart it may log fatal via syslog; image boot records a fatal/info "boot after downtime" event when possible. Watchdog is outside the image; do not pretend Nopales can restart itself after a hard process death.

V1 CUT (shipped) - Ops_log ring + stderr mirror - Ops_stats request counters + auth_log login counts - GET /analytics page (kernel) - Fingerprint store in data_rows ops-incident - Auto-file note+todo on new error/fatal - Template body first; LLM enrich if Ai path available - (log-tail) (ops/summary) prims Defer: multi-week charts, bot ML, off-box shipping.

horizon

Long-term possible futures built on this substrate (design only)

[status: implemented]

Possible futures (not commitments):

A. Personal computing environment Always-on personal image; notes/CRM/automations as live functions; browser as desktop.

B. Multi-user community OS system/main commons; personal garden branches; merge reviews; author-runs-as-author capabilities.

C. AI-native software workshop AI cohabits image; proposes types+fns+routes as app sketches; binding-level diffs; provenance; later addressable AST patches.

D. Internal tools platform Team branches; shared business objects; live inspectable tools without redeploy for Nopales-tier changes.

E. Education / research lab Legible multi-user systems + PL teaching with forks/merges and visible isolation.

F. End-user programmable products Friendly skin on same substrate; templates as starter branches; AI drafts, users edit.

G. Hardened multi-tenant service Solo5, real SSH + web login, argon2, mTLS, fleet policies, true setuid data scoping.

H. Dabar – live Bible study libraries BSB reader + Strong's + interlinear as load-library packages (bible/ + dabar/) on the image; not a separate OS. Spec: dabar.borg (root-inlined chapter). Semantic search deferred.

Milestone ladder: now – hacker env + browser login + Nopales product shell (define/edit/route/AI; ui/nav ui/home; auth session) next – product theme Path B (css/* + ui/theme); kill silent OCaml product defaults (nav/home/CSS); emergency-only chrome+css; shell denser; branch promote UI later – environment feel (more system UI in Nopales, permissions, multi-user fleet isolation) horizon – community + AI coworker + Solo5 product

Branch UX + software updates: see branching.borg subsections personal-workspace (implemented), package-updates / promote / branch-browser-ui (planned). Defaults on system/main; garden on <user>/personal; promote is selective merge + git.

Principles to preserve: live system over file tree; store is truth; code branches / data shared; functions compose; AI is an author not god mode; inspectability; isolation by process.

> – *agent note:* 2026-08-02: design-only futures doc; implemented as spec-complete.

19 borge/notes.borg

pricklypear-notes

Pricklypear book chapter: notes – outline-first personal knowledge (org-roam / org-mode / Obsidian-shaped) as Nopales on the one-tree substrate

[status: partial]

> – *agent note:* 2026-08-02 status reconcile: core notes surface is live (doc/get, /notes, search, wiki, roam). Remaining partial: outline-actions (op-protocol refile + full structed set), garden-import (pass-2 uuid edges), tree-cutover finish slices.

notes

Outline-first notes OS: tree documents, wiki links, dailies, capture, hypermedia structure edit, garden import

[status: partial]

> *[verify] build: dune build image; smoke: (load-library "outline") then pure tree ops on a sample node tree; smoke: (load-library "notes") installs /notes and notes/*; smoke: create note with nested outline; GET /notes?slug=? shows foldable tree; smoke: [[slug]] in node body becomes link; backlinks partial lists inbound; smoke: (bible Gen 2 3) in body renders dabar href; unknown book degrades; smoke: (notes/daily) get-or-creates today's daily outline; smoke: pp_eval '(notes/get "?")' returns outline value for agents; smoke: tree: folder + note + heading children round-trip via notes/doc/*; smoke: import dry-run of vault md reports counts without writing*

========== PRODUCT INTENT ==========
Build a personal knowledge environment on the live image inspired by: - org-mode: hierarchical OUTLINES as the document model - org-roam: stable ids/slugs, backlinks, dailies, capture - Obsidian: fast browse, wiki links, folder garden

NOT a port of Electron Obsidian or Emacs. NOT continuous file-backed markdown under libs/ or disk. Notes are durable TREE NODES in Postgres, edited live. One-shot vault import (Obsidian md) is in-scope; sync is not.

WHY THIS OS: Every note/outline is a Nopales value. Agents and humans use the same functions via REPL / pp_eval / htmx. No notes REST API to invent – the image is the API.

========== PRIORITY ORDER (locked) ==========
1. One-tree note substrate (folders, notes, heading children) 2. Outline algebra on heading nodes (structed/outline ops) 3. UUID wiki links + backlinks; bible sexp refs ? dabar 4. Personal garden isolation (not system/main content) 5. Daily notes + capture / inbox 6. Migrate existing PP notes; import Obsidian vault md 7. Tags / search polish – RESOLVED by subsection search-modal 8. Graph visualization (optional, late)

========== PACKAGES – dependency layering (HARD RULE) ==========
The packages form a STRICT LAYERING. A lower layer may not import a higher one. Drift here is a bug, not a style choice.

outline/ – pure tree ADT + structure ops. NO storage, NO notes/, NO roam/. Leaf. Reusable by todo/, plan/, kanban/, tests. structed/ – generic structural-edit algebra. Leaf. bible/ + dabar/ – reader + study; bible sexp render target. May be read by outline render dispatch via a hook passed in, never by import. roam/ – link parse / reindex / render. LEAF over outline + prims only. Does NOT call notes/doc/* or notes/*; callers pass titles/slugs

in. notes/ – persistence fa?ade + routes + capture + dailies + structure-op dispatch + UI. The ONLY package that touches the note store (tree_* / data_rows migrate). Calls outline/, structed/, roam/, bible/ downward. Owns roam/reindex on content writes (notes ? roam, one-way).

ALLOWED EDGES: outline ? structed ? notes ? {roam, bible} roam ? outline (read-only ADT) FORBIDDEN: outline ? notes, outline ? roam, roam ? notes (cycle), notes ? notes (two fa?ades – see storage FA?ADE rule).

========== WHERE IT GOES (routing table – one home per concern) ==========
node ADT (id/title/body/todo/kids), encode/decode, find/update/insert/delete/promote/demote/move, archive/cycle-todo, valid?, todos scrape ..... outline/ generic tree surgery (slurp/barf/wrap/splice/raise) structed/ note read/write/list/search/folder, daily, capture, set-folder, op dispatch (apply-op, node-op, eval), routes + partials + page HTML, backlinks panel host .. notes/ [[slug]] parse, note-link reindex, backlinks query, wiki/media render, render-body ..... roam/ (bible ?) sexp ? /dabar href, abbrev parse ..... bible/+dabar/ legacy data_rows note ? tree migration (one-shot) .... notes/migrate/

========== PACKAGE FILE LAYOUT (one source of truth) ==========
Each package is ONE file: libs/<pkg>/lib.pp. The image seeds libs/<pkg>/lib.pp only (session.ml discover_seed_packages scans top-level dirs). Subdirectory lib.pp files under libs/notes/{outline,capture,doc,refile, tree,ui,migrate}/ are NOT loaded; they are stale pp_sync snapshots and MUST NOT be maintained as a second source. pp_sync pull <pkg> regenerates the single libs/<pkg>/lib.pp from the live branch; that file is canonical in git. Do not re-split notes/ into subdirs without first teaching the loader to stitch them – until then, one file.

========== OUT OF SCOPE (v1) ==========
- Full org-mode syntax (drawers, babel, agenda, clock) - Full CommonMark / markdown WYSIWYG - Force-directed graph as launch requirement - Continuous Obsidian/FS vault sync (one-shot import only) - TeX/PDF/video/EXPORT pipeline ingest from vault - Doltgres / DB engine swap for note history - Per-note function_defs (notes are data, not code) - Real-time multiplayer CRDT on one outline - Full per-lens versioned /data (one-tree placement B); garden isolation is path+author scoped (see personal-garden)

outline-model

Sexp outline ADT: node tree with stable ids – org structure as data

[status: verified]

> *[verify] smoke: outline/node constructors and outline/html produce nested details; smoke: outline/promote demote move-up move-down preserve ids; smoke: round-trip: print tree text then parse back (or JSON props path)*

CANONICAL SHAPE (implementation may use lists/dicts):

A node is a record with: id – stable string (uuid or short id), required title – string, required body – string, optional prose (may contain [[slug]]) todo – "" | "TODO" | "DONE" | future keywords kids – list of child nodes (order matters)

Suggested Nopales construction helpers:

(outline/node title) (outline/node title body) (outline/node* props kids) ; props = alist or dict JSON

Tree = root node. In-memory ADT unchanged. Persistence is heading children under the note path (notes.storage); the legacy fields.outline JSON blob is retired after cutover.

WHY SEXPS: Nested lists ARE outlines. No heading-level parser. pp_expr / pretty printers already exist for readability. Structure edit = pure functions on values.

PATHS: Prefer id-based addressing over index paths so reorder does not break ops: (outline/find tree id) -> node | nil (outline/update tree id f) -> tree (outline/insert-child tree parent-id new-node) -> tree (outline/delete tree id) -> tree (outline/promote tree id) / demote / move-up / move-down

FOLD STATE: v1: browser <details> open attribute only (ephemeral). Optional later: collapsed-ids set in note props or session.

PRINT/PARSE: In-memory: list/ADT via outline/* constructors. On disk after cutover: one heading tree_node per outline node (notes.storage). encode/decode helpers still exist for import, tests, and whole-subtree replace serialization.

PURE PACKAGE (enforced by PACKAGES layering): libs/outline/lib.pp must not touch storage and must not import notes/ or roam/. It is a leaf reusable by other apps (todo/, plan/, kanban/, tests). Two current leaks to close: - outline/render-body dispatches roam/render-body + bible/render-body. Move that dispatch UP to the notes/ UI renderer (the call site outline/html-node is already UI-flavored). outline/ stays pure; the renderer in notes/ picks roam vs bible by inspecting the body. - outline/extra-actions calls notes/refile/extract-form. Move the refile-action injection up to the notes/ caller that assembles the node action menu; outline/ emits a neutral action slot or takes the extra-actions as an argument.

storage

Notes as one-tree nodes: folders, note leaves, heading children; notes/* fa?ade

[status: implemented]

> – *agent note:* 2026-08-02: notes/doc/* fa?ade on tree (libs/notes/doc + lib.pp); live (notes/doc/get "agents") returns uuid/slug/title/outline; tree/garden-root path grammar in tree_store.ml.
>
> *[verify] smoke: notes/upsert then notes/get by slug returns outline; smoke: second upsert same slug updates in place (idempotent); smoke: folder path nesting depth > 1 via tree list; smoke: outline headings persist as heading children under note path; smoke: rename/move note keeps uuid; links still resolve; build: dune build image*

==========

ONE-TREE NOTES (replaces flat data_rows note blob) ==========

Flat CRUD (get/create/update/rows on type note) remains for other product types. Notes leave that path. See also the index-read-path subsection for how every read (index + detail) resolves to the one tree store and how the legacy rows fallback is retired.

PATH GRAMMAR (hierarchical; not data.<type>.<uuid>): data.note.u.<user>.? – user garden root data.note.u.<user>.<folder>? – folder (kind=folder) data.note.u.<user>.?.<slug> – note leaf (kind=note) data.note.u.<user>.?.<slug>.h.<nid> – outline heading (kind=heading)

Readable slug labels: [a-z0-9-]+ only (ltree-safe). Type name segment stays literal "note" (not enc_label base64).

KINDS (tree_nodes.kind; reverse-mirror ignores these – they must NEVER be written as kind=datum or path segment-3 will be misread as a uuid by tree_from_nodes): folder payload body: {uuid, title} note payload body: {uuid, slug, title, tags, kind, day, source_id?, source_path?} NO outline blob – children are truth heading payload body: {id, title, body, todo} kids = real child heading nodes under path

IDENTITY: uuid – stable; wiki links and refile target this slug – last path label of the note; globally unique per user garden (enforce on upsert) title – display only; independent of slug

OUTLINE LOAD/SAVE: In-memory ADT stays outline/* + structed/* (id title body todo kids). Load rebuilds ADT from heading subtree. Save v1 may

whole-replace heading children under note.h in one transaction; fine-grained op?tree/move is a tighten pass, not a blocker.

FA?ADE – ONE, not two (HARD RULE): notes/doc/* is the SOLE note persistence fa?ade. Every read/write/list/search/folder op goes through it; internals call tree prims, not (create 'note ?). Agent and UI ABI is notes/doc/get|upsert|list|set-folder|?. The legacy flat notes/* fa?ade over data_rows (notes/get, notes/upsert, notes/row, notes/make-fields, notes/apply-op, notes/capture, notes/refile 3-arg, notes/get-outline, notes/get-title, notes/do-save, notes/ensure-inbox, notes/daily, notes/cycle-node-todo, notes/node-op) is RETIRED. It is not reachable from any route and must be deleted from libs/notes/lib.pp; nothing may call it. New work adds to notes/doc/* (or notes/<feature>/* under the notes/ package), never revives notes/<flat> names. notes/doc/* accessors (notes/doc/title, /outline, /tags, /kind, /day, /folder) replace the legacy notes/get-* ones.

KERNEL PRIMS (tree_store + thin register; additive): (tree/get path) (tree/list prefix [depth]) (tree/upsert path kind type body-json) (tree/delete path [recursive?]) (tree/move old-path new-path) – subtree path rewrite (tree/find-by type field value) (tree/get-uuid uuid) Flat get/create/update/rows ABI unchanged for todos/etc.

NOTE-LINK: see links-and-roam (UUID edges).

NOT IN function_defs / system/main seed: Note *content* is never package defaults. pp_sync does not pull garden notes. notes/* outline/* roam/* CODE may promote to main; content stays in the user garden path.

LEGACY: Existing data_rows type=note rows migrate once (M0) into tree nodes; after cutover notes/* does not write them. folder string field and JSON outline field are retired. M0 must EXPLODE each outline blob into real heading child nodes under the note path (no inline outline blob), and normalize path labels to the kebab slug. After every uuid verifies in the tree, the legacy data_rows type=note rows are DELETED (no permanent inert archive).

HISTORY: v1 overwrite on save (updated_at). No Doltgres.

links-and-roam

Wiki links [[slug]] as UUID edges; bible sexps ? dabar; media embeds
[status: implemented]

> – *agent note:* 2026-08-02: libs/roam (parse-links via extract-links prim, reindex note-link from_uuid/to_uuid, backlinks, render-body/media); live roam/backlinks on agents. Refile still ad-hoc package not op-protocol – tracked under outline-actions.
>
> *[verify] smoke: body with [[other]] creates note-link UUID edge on save; smoke: (roam/backlinks slug) lists inbound links after resolve; smoke: render turns [[other]] into anchor using current slug/title; smoke: move/rename note does not require reindex; links still resolve; smoke: refile/extract of a node does not require roam/reindex (uuid stable); smoke: [[media:uuid|alt]] renders img; not indexed as note-link; smoke: (bible Gen 2 3) renders /dabar href; (bible ?) not a note-link; smoke: Obsidian [[bible:Genesis2:3|?]] import normalizes to bible sexp; smoke: (extract-links body) matches roam/parse-links edge cases; test: image primitives_test extract-links cases*

==========

NOTE-LINK = UUID EDGE (not slug pair as source of truth) ==========

TYPE note-link (data row or tree datum – implementation choice; shape is what matters): from_uuid – source note uuid (stable) from_id – source heading id ("" = whole-note) to_uuid – target note uuid (stable) to_id – target heading id optional label – optional display label kind – "wikilink" | future Optional cached from_slug/to_slug for debug only – never authoritative. Index by (from_uuid, to_uuid). Live package: libs/roam (parse-links, reindex, backlinks, render-body, backlinks-html).

ROAM IS A LEAF (enforced by PACKAGES layering): roam/ imports outline/ (read-only ADT) and prims only. It MUST NOT call notes/doc/* or notes/*. The two current roam?notes calls are removed by pushing the lookup up to the notes/ caller: - roam/backlinks needs source titles for display ? the notes/ui backlinks panel resolves titles/slugs from the rows roam returns (uuid + from_id + label), or roam returns uuid/id/label only and notes/ui decorates. - roam/render-link resolves the target note row ? pass the resolved (slug,title) IN from notes/ui; roam renders the anchor from args, or notes/ui renders and roam just supplies the parse. roam/reindex is called BY notes/doc on content writes (notes ? roam, the one allowed direction); roam never calls back up into notes/doc to resolve a uuid.

AUTHORING SYNTAX (bodies, still human-friendly): [[slug]] – wiki by slug at write time [[slug|label]] – labeled wiki [[media:uuid|alt]] – media embed (not note-link) (bible BOOK ch [verse]) – sexp bible ref (not note-link) (bible BOOK ch verse-from verse-to) – optional range BOOK accepts full name or bible abbrev (Gen, John, ?); normalized via bible/abbrev-of + bible/parse-ref helpers. No #node-id deep links v1.

SAVE-TIME RESOLUTION: [[slug]] -> lookup note uuid (tree/find-by / notes/doc); store edge uuid?uuid. Missing target: stub-link without edge until target exists (prefer). Bible sexps are NOT note-link rows.

REINDEX: (roam/reindex note-uuid outline-tree) replaces edges for from_uuid. Called on content-touching saves only (set-body, upsert with body change, op=eval target=body). Move/rename/refile/extract does NOT reindex – note and heading uuids/ids stay stable; edges remain valid. Cached from_slug/to_slug may go stale; resolve via uuid at read.

========== REFILE / EXTRACT vs LINKS (align tree-browser + op-protocol) ==========
Refile and extract are STRUCTURAL moves of outline subtrees across note documents – they are NOT link-graph operations. Today: libs/notes/refile (ad-hoc dual upsert). Target: structural-editing.op-protocol owns the wire POST {op, target, args} ? fragment + OOB selection named ops e.g. refile / extract-note with args (dst-slug) or (new-slug?) – server applies pure tree surgery then whole-doc write via notes/doc/*. image.tree-browser deliberately defers refile/move UI until those ops exist on the shared protocol (no parallel /tree/refile routes). notes.outline-actions already lists this gap. When protocol lands: - notes/refile and notes/refile/extract become thin adapters or disappear into op dispatch - roam edges need no rewrite (uuid stable) - tree-browser may offer move only via the same ops

RENDER: Wiki: resolve to_uuid ? current slug/title/path; anchor /notes?slug=<current>. Broken uuid ? muted missing. Media: unchanged img path. Bible sexp: template via bible/dabar – (bible/link-html book ch verse [label]) -> ? optional hx-get into #dabar-panel when chrome present. Kernel extract-links / render-links gain bible-sexp recognition (budget-safe OCaml), or Nopales pre-pass normalizes sexps before render-links – prefer OCaml once syntax is frozen.

IMPORT NORMALIZE (garden-import): Obsidian [[bible:Genesis2:3|Label]] and bare [[bible:Hosea4:6]] become (bible Hosea 4 6) text in heading bodies (Label dropped or becomes visible prose adjacent – keep label as link text via (bible Hosea 4 6 "Hosea 4:6") if three-or-four arg form includes optional label string).

QUERY: (roam/backlinks slug-or-uuid) -> inbound with current titles/slugs for display. UI partial: notes-backlinks.

NOT v1: - graph view renderer - unlinked-mentions auto-discovery - block-ref transclusion - path-qualified wiki links for duplicate slugs - tree-browser-initiated refile (waits on op-protocol)

budget-scale

Per-call eval budget: stress contracts for notes/roam/outline so large trees and bodies never Budget_exceeded on ordinary UI/agent paths

[status: implemented]

[verify] build: dune build; test: dune runtest – lisp list-hof + image extract-links; smoke: scripts/verify_budget_stress.py (monitor-rerunnable); smoke: parse: 500+ wiki links in one body completes; count matches; smoke: reindex/upsert: 10 nodes x ~8k body with links indexes all links; smoke: render: outline/html on large tree/body returns HTML, no budget error; smoke: lazy: a many-node note opens with eager-depth nodes only; expanding a collapsed node fetches its subtree partial; no budget error; smoke: many-node ops: N structure ops each in own eval (HTTP-shaped); smoke: (budget-remaining) positive mid-call; floor asserted after stress cases

WHY: The 100k step default_limit is a safety net, not a perf governor. Char-scanners and recursive list walks in Nopales burned the budget on ordinary notes (upsert reindex, large inbox render) while the write sometimes committed first – silent stale links. Hot paths move to OCaml or kernel special forms; stress tests guard regressions.

BUDGET MODEL (lisp-interpreter.eval): - One budget per eval/call_handler invocation - tick on each eval step; Budget_exceeded aborts that call - OCaml prims cost one tick at the call site (body free) - (budget-remaining) -> steps left (dynamic current budget) - (bench expr-string [n]) -> avg us/iter for calibration Do NOT "fix" scale bugs by raising default_limit.

KERNEL / HOT PATHS (required): - list/map, list/filter, list/foldl: special forms (OCaml loop + apply); not O(n) Nopales recursion frames - extract-links: OCaml; roam/parse-links uses it - select-for-update: error outside with-transaction (reliability adjacent to long evals) Planned if stress fails render/tree: OCaml render-links (or roam/render-body prim) cheaper outline encode/decode/find if tree ops dominate

STRESS SUITE (scripts/verify_budget_stress.py): Monitor-rerunnable against a running image (dev or habitat) via pp_eval. Synthetic fixtures only – do not mutate user garden notes without a dedicated test slug prefix (e.g. budget-stress-*) cleaned up after.

Suites: 1. PARSE / EXTRACT - correctness edges (3 links, 0, unclosed, [[]], media) - scale: single body with >=500 links completes - optional: 10k-char link-free body still cheap 2. REINDEX / UPSERT - tree: >=10 nodes, each body >=8k with >=1 link - notes/doc/upsert returns ok (not budget exceeded) - note-link count for slug == expected wiki links - budget-remaining floor after call (implementation picks a conservative floor; document in script) 3. RENDER - outline/html (or show-body without request deps) on large tree: many nodes and/or one ~32k+ body - must return non-empty HTML string; no budget error - wiki + media syntax appear as anchors/img when hook is roam/render-body 4. MANY-NODE ACTIONS - create synthetic note with >=50 child nodes - each op in its own eval (mirrors HTTP call_handler): cycle-todo, move-up/down, archive, set-title - extract one node to its own note; refile one node - every op ok; final tree consistent; cleanup slugs 5. THRESHOLD PIN (optional / nightly) - binary-search max body size for parse vs render - log or store result; not a hard CI flake gate unless threshold collapses below known-good baseline

ACCEPTANCE: verify_budget_stress.py exits 0 on local dev.sh image and on habitat after deploy. verify_notes_execute_all.py remains the broader feature smoke; budget script owns scale. Failures file as product bugs (reindex/render), not "raise the limit".

OUT OF SCOPE HERE: - Jane Street Incremental / BI pipelines - raising default_limit as the primary fix - preemptive multi-request chunking of a single note view

outline-actions

Per-node outline action menu; the eval op turns nodes into a live Nopales surface

[status: partial]

– *agent note:* 2026-08-02 confirm still partial: notes/outline/apply-op + eval + POST /partials/notes-node-op shipped; notes/refile* exist but not on structural-editing.op-protocol; full structed wrap/splice/raise not all on outline menu.

[verify] smoke: structure ops: add-child/sibling delete move promote/demote archive cycle-todo set-title/body; smoke: slurp-forward / barf-forward via structed/ on outline accessors; smoke: op=eval target=child splices returned string as a new child node; smoke: op=eval target=sibling splices; target=body replaces this node body; smoke: eval expr binds self/doc/slug to current context; smoke: eval reindexes roam links when a body changes; smoke: refile: node moves to another note root kids; smoke: refile destination is a lazy typeahead modal – the note page never enumerates the garden (BORGE-1785603757); smoke: extract: node becomes its own note; removed from source; smoke: POST /partials/notes-node-op returns outline partial + selection; smoke: scripts/verify_budget_stress.py many-node actions suite*

SHIPPED SURFACE (libs/notes/outline + outline + structed): notes/outline/apply-op dispatches structure ops on the outline tree value. Ops present today: add-child add-sibling delete move-up move-down promote demote set-title set-body set-todo cycle-todo archive unarchive slurp-forward barf-forward (via structed/* + outline/kids outline/set-kids – op-protocol preview) Selection companion: notes/outline/apply-op-sel ? (list tree' sel) for OOB restore.

WIRE (reconcile – code wins over older spec path): POST /partials/notes-node-op params: slug, op, node-id [, title|body|todo|expr|target] NOT /partials/notes-op (stale name). Fragment path ? no chrome (wants_fragment). Client hx-target #outline hx-swap outerHTML; selection via hidden OOB when present.

op = eval Form: notes/outline/eval-form ? same partial endpoint. notes/outline/eval-result loads (lambda (self doc slug) <expr>) and applies it. target in {child, sibling, body} via notes/outline/eval-target (default child). result handling by target: body as-str ? outline/set-body on node child string ? new node title; valid outline node sexp ? splice subtree under id sibling same as child, insert after id

REFILE / EXTRACT (libs/notes/refile – NOT yet op-protocol): notes/refile src-slug nid dst-slug – detach node from src outline, add-child under dst root, dual upsert. notes/refile/extract – detach ? new note slug from title, remove from source. These are whole-doc outline writes via notes/doc or legacy notes/upsert. When structural-editing.op-protocol lands for cross-doc moves, refile/extract MUST become named tree-ops on that protocol (same POST shape, server-authoritative tree), not parallel ad-hoc routes. image.tree-browser defers refile/move UI until then.

REFILE DESTINATION UI (lazy modal, BORGE-1785603757): No note page renders an eager <select> of all notes – that O(n) notes/refile/options over (notes/doc/list) blew the 100k step budget at garden scale. Refile target picking is a lazy htmx modal: the toolbar 'refile' <details> and GET /partials/notes-refile?src=SLUG both render notes/ui/refile-modal-body – a typeahead over /partials/notes-search?mode=refile (filtered in Postgres, no garden enumeration) plus a raw slug input for agents / keyboard-only users. The legacy eager builders (notes/refile-form, notes/refile/form and the O(n) notes/refile-options / notes/refile/options) are REMOVED. notes/refile/move performs the detach+attach write.

PERSISTENCE: Structure ops upsert through notes/doc/* (tree store). Body-touching ops should roam/reindex (verify smoke).

WHY: Notes view = live Nopales surface. wiki-llm-loop is the first major consumer of op=eval splices.

SECURITY: eval runs full session prim set incl DB – treat as REPL. Auth gate only boundary v1; v2 may confirm destructive prims.

GAPS (keep status partial until closed): - full structed op set (wrap/splice/raise/?) not all wired into apply-op / keymap - refile/extract not on op-protocol wire

yet - budget stress suite must stay green on garden-scale

wiki-llm-loop

LLM-maintained wiki over the notes corpus – ingest, query, lint as Nopales ops
[status: implemented]

> – *agent note:* 2026-08-02: libs/wiki/lib.pp – wiki/ingest-from-source, wiki/query, wiki/lint, wiki/events, wiki/schema, wiki-event rows; live wiki/schema ok.
>
> *[verify] smoke: (wiki/ingest-from-source TEXT) creates/updates a source note + entity/concept notes + note-link rows; smoke: (wiki/query QUESTION) synthesizes with [[slug]] citations; may file-back a kind=query note; smoke: (wiki/lint) returns orphans/contradictions/missing-pages/suggested-sources; smoke: each top-level wiki op writes one wiki-event row; (wiki/events) lists them; smoke: agents drive ingest/query/lint via eval (pp_eval); no /wiki/* routes require registration*

PATTERN: A persistent, compounding wiki over curated sources: the LLM does not retrieve raw chunks per query; it reads the existing corpus, integrates each new source into the notes (page updates, cross-links, contradiction flags), and keeps synthesis current. The corpus IS the knowledge base.

SHAPE: Notes ARE wiki pages; kind discriminates role. The agent drives operations through ordinary Nopales functions exposed to the REPL; the user reaches the same operations through the outline-actions eval op on a source node. No /wiki/* routes for v1 – the existing /notes surface plus the live eval surface cover the user-facing flow.

BUILD ORDER (dependencies): 1. image.per-request-context – so notes routes survive the cotenant race: anonymous attach flips the shared Session.t routes/env mid-request and any personal-branch route 404s under traffic until per-request-context lands. Deployable on system/main as a documented workaround in the meantime. 2. notes.links-and-roam (note-link rows + roam/parse-links + roam/reindex + roam/backlinks). 3. notes.outline-actions (the eval op for LLM splices).

NOTE KINDS (convention over the existing note row schema; widening the note.kind vocabulary – no new storage): note existing default (behavior preserved) daily existing dailies source source-summary page (per ingested raw source) entity a named thing (person, place, work) concept an abstract topic query a filed-back synthesis with citations synthesis cross-source integration/comparison schema the corpus preamble note (see below) log reserve; not used v1 (audit is wiki-event rows)

DOC-LEVEL FRONTMATTER (extends the note row, NOT per-node metadata – avoids a node-schema migration): updated_at timestamp of last ingest/query touch updated_by "llm" | username | "agent" source_count for source/entity/concept: number of distinct sources contributing; incremented on ingest

SCHEMA-NOTE CONVENTION: A note with kind=schema holds prose describing this corpus's conventions, page disciplines, and ingest emphasis; co-evolved by the human and the LLM. (wiki/schema) returns its body string, seeded with a sensible default at first call. ingest/query/lint read it as the LLM preamble. There is no separate schema-agent path – it is just another note the loop reads.

OPS (each is one top-level Nopales call; each writes one wiki-event row on success): (wiki/ingest-from-source source-text [slug-hint]) 1. create/update a source note (kind=source) carrying the source text + extracted summary outline. 2. read (wiki/schema) + (roam/backlinks)/index over the current corpus; build the prompt. 3. (ai/ask prompt) -> a JSON plan: { summary_node, entities[], concepts[], links[{from,to,kind}], followups[] } 4. notes/upsert each

entity/concept page (kind=entity | concept), composed with the source's contribution; bump source_count; stamp updated_at / updated_by. 5. (roam/reindex) the affected slugs. 6. write one wiki-event row (kind=ingest, op-slug, ts, summary). Return the new source-summary slug + the list of pages touched.

(wiki/query question) read (wiki/schema) + the most relevant pages (roam / find-text over the corpus index); synthesize with [[slug]] citations. Optionally file-back as a kind=query note that child-references its cited pages. One wiki-event row (kind=query).

(wiki/lint) one (ai/ask) pass over schema + index + note-link edges; report orphans, contradictions, stale claims, missing pages (concepts mentioned but lacking their own page), suggested new sources. Optionally draft stubs for missing entities (opt-in create-stubs? arg). One wiki-event row (kind=lint).

AUDIT: TYPE wiki-event (rows; fields: kind op slug ts summary): append-only, branch-shared, one row per top-level wiki op (ingest/query/lint). NOT autonomic – only these three top-level ops write events. Helper calls (roam/backlinks, outline/eval, etc.) do not write events. Retention is opt-in: (wiki/events [since]) -> list recent events (wiki/prune-events days) -> drop events older than N days (explicit, manual) Corpus content evolution is recorded in the notes themselves (updated_at/by frontmatter); the wiki-event stream is operational audit, not content of record.

LIVE TELEMETRY (separate stream, unchanged infra): ingest/query/lint emit Info/Error into the existing Ops_log ring (component "wiki") so a long op is visible via (log-tail). Bounded 5000 + rotates; not a permanent audit. Two streams, two purposes: Ops_log = live observability of this request; wiki-event rows = audit trail of what the wiki has done to itself.

NOT v1 (deferred): - URL fetch / clipper (user pastes text first) - markdown (outlines ARE the substrate; no marked.js) - graph view renderer (note-link rows hold the structure) - unlinked-mentions auto-discovery - block-ref transclusion - images / attachments - batch / unsupervised ingest sweep

dailies-and-capture

Daily outlines and quick capture (org-roam-dailies / org-capture shaped)
[status: implemented]

> *[verify] smoke: (notes/daily) returns same slug for same day on second call; smoke: (notes/capture title body) creates inbox-tagged note or appends; smoke: GET /notes/daily opens today*

DAILY: slug convention: daily-YYYY-MM-DD kind = "daily", day = YYYY-MM-DD (notes/daily) / (notes/daily "2026-07-11") get-or-create root outline with title "Daily YYYY-MM-DD" UI: /notes/daily , menu link under apps or notes

CAPTURE: (notes/capture title body) -> new slug (slugify title + short id), tags include inbox, kind note, outline = single node with body Optional: (notes/capture-to slug title body) appends a child node under root (inbox into a project outline)

INBOX REVIEW: /notes?tag=inbox list partial – phase 2.

hypermedia-ui

Routes, partials, structure-edit via htmx; menu entry
[status: implemented]

> *[verify] smoke: GET /notes lists recent notes; smoke: GET /notes?slug=? full page with chrome + outline; smoke: GET /partials/notes-outline?slug=? fragment no chrome; smoke: structure op POST returns updated outline partial; smoke: ui/menu can link Notes without breaking other apps; smoke: note page does not enumerate all notes (refile target is a lazy typeahead, not an eager <select>)*

ROUTES (full page = chrome; /partials/ and HX-Request = fragment):
GET /notes GET /notes?slug=NAME GET /notes/daily GET /notes/edit?slug=NAME ; optional dedicated editor POST /notes ; create / save / capture GET /partials/notes-list GET /partials/notes-outline?slug= GET /partials/notes-backlinks?slug= GET /partials/notes-node?slug=&id= ; lazy subtree returns one node's <details> subtree HTML POST /partials/notes-op ; structure edit params: slug, op, id, ?

STRUCTURE OPS (POST notes-op): op = insert-child | delete | promote | demote | move-up | move-down | set-title | set-body | set-todo Always reindex links if body changes. Response: outline partial HTML (hx-swap target #outline)

RENDER: Prefer <details class="ol-node"> fold (no heavy JS tree). Ops as small buttons on each row (htmx).

LEAN NODE RENDERER (outline/html-node): Each node is emitted with the fewest html/* calls feasible – constant attribute fragments are precomputed at library load and assembled with direct string-append, not via the fine-grained html/attr / html/attrs / html/span DSL on the hot recursive path. The DSL stays available for page chrome and one-off fragments; the recursive outline renderer is the budget-critical path and must not compose dozens of function applications per node.

LAZY SUBTREE LOADING: Eager rendering is capped at a shallow depth (root + its direct children). Deeper nodes render as a collapsed <details> whose body is fetched on first expand via hx-get=/partials/notes-node?slug=&id=, swapped in place. This bounds per-render html-skeleton cost by the eager depth, not by total node count, so a large note never Budget_exceeded on ordinary open. The partial returns the same html-node markup the eager path would have produced for that subtree, so eager and lazy nodes are visually identical. Structure ops still re-render and swap #outline.

MENU: Add (menu/link "notes" "/notes") under apps in default ui/menu when notes is dogfood-stable; or document manual ui/menu edit + pp_sync pull.

COMPOSITION: notes/page embeds partials like todo/page embeds todo/list-html – same hypermedia discipline.

index-read-path

Notes index reads resolve to the tree store exactly once; legacy data_rows fallback retired; interim read-layers removed

[status: implemented]

> *[verify] smoke: GET /notes lists garden folders incl. tree-only notes; smoke: GET /notes?folder=garden/bible/scripture_concepts lists its notes; smoke: (notes/list-light) equals notes/doc/index-list (both tree); smoke: (notes/doc/get slug) and /notes?slug=? agree for tree-only slug; smoke: no binding under notes/light/* remains on the image; smoke: no call site of (rows 'note) outside notes/migrate/legacy-**

PROBLEM (drift this closes): The index accumulated overlapping read layers while the one-tree cutover was landing: notes/doc/* – dual-read fa?ade (tree first, legacy data_rows fallback) notes/ui/* flat – budget-safe flat index over notes/doc/index-list (tree via OCaml tree/note-index) notes/tree/render – original nested folder tree; walks folders with Lisp list ops; exceeds the eval budget at garden scale notes/light/* – live-only nested index reading legacy data_rows ONLY; became the routed /notes handler, so tree-only (garden) notes vanished from the UI while agents (fa?ade) still saw them One /notes route pointed at whichever layer happened to be loaded last. Result: index and detail disagreed; garden invisible in UI; budget-safe code unreachable.

TARGET – ONE READ PATH: Every notes read (index and detail) resolves through notes/doc/* to the ONE tree store exactly once: index /notes

? notes/page ? notes/ui/folders-html (flat, budget-safe via OCaml tree/note-index) detail /notes?slug=? ? notes/ui/show ? notes/doc/get agent notes/doc/get|list|search – unchanged (fa?ade) notes/list-light is re-pointed at notes/doc/index-list so agent and UI see the same rows.

SLICES: I1 Route /notes to notes/page (git-managed, flat index). Delete the live-only notes/light/* bindings; nothing in libs/ references them. I2 Retire notes/tree/render + render-folder (budget- unsafe at garden scale). Keep only as an explicitly renamed non-routed legacy binding, or delete. I3 notes/list-light ? notes/doc/index-list (same rows, same order); drop its private legacy-rows read. I4 Retire the legacy data_rows fallback in notes/doc/* (list / row / find-slug). Tree is the only store. Precondition: M0 (migrate legacy ? tree) verified for every legacy uuid; legacy rows kept as an inert archive, not read. Audit gate: no call site of (rows 'note) / (find-rows 'note) outside notes/migrate/legacy-*.

AUDIT (I4 gate): Full-tree scan of libs/ + image/ confirms every note read outside the fa?ade's own fallback already goes through notes/doc/* – no package (todo/roam/wiki/flashcards/bible/ dabar/ai/calendar/capture/ui) reads rows 'note directly. Only notes/migrate/legacy-* touches legacy, by design. I4 is therefore a fa?ade-internal deletion, not a cross-package change.

NON-GOALS: - Re-raising the eval budget to save notes/tree/render (budget is a safety net; the nested Lisp walk is the bug, per budget-scale) - Changing the slug-page outline editor or structure ops - Merging/renaming garden folders for display (kebab vs underscore is cosmetic; path-based folders tolerate both). Folder GROUPING is path-derived (not the legacy folder string), and the garden/ import prefix strips to top level in the index per garden-import DISPLAY.

CUTOVER COMPLETION (the finish line this subsection gates): The legacy nested index (notes/light/*) must actually be deleted from the image (I1) so /notes serves the flat budget-safe index over tree/note-index, and that index groups by PATH-derived folders with the garden/ prefix stripped to top level. Until then the UI shows only the legacy-folder rows and hides garden/tree-only notes. Legacy data_rows type=note rows are DELETED after M0 re-migration verifies every uuid (no permanent archive).

F6 DEAD SUBPACKAGE DIRS (libs/notes/<sub>/lib.pp): The subdirectory files libs/notes/{outline,capture,doc, refile,tree,ui,migrate}/lib.pp are NOT loaded by the image (loader scans top-level libs/<pkg>/lib.pp only) and have drifted from the canonical libs/notes/lib.pp (e.g. stale notes/outline/apply-op missing op-seq 409; notes/capture/ title truncation differs). They are a readability hazard – a maintainer opens the subpackage file thinking it is authoritative. DELETE the subdirectory lib.pp files; the single libs/notes/lib.pp is canonical (see PACKAGES file layout). Backups/ may retain old copies. This slice is pure deletion; no route or binding changes.

agent-access

Agents use notes via eval – no separate notes HTTP API

[status: implemented]

> *[verify] smoke: pp_eval notes/list and notes/get; smoke: agent-task tool list may include notes_search later*

LAPTOP / PI: scripts/pp_eval.py '(notes/daily)' scripts/pp_eval.py '(notes/search "sync")' scripts/pp_eval.py '(notes/get "pp-design")'

IN-IMAGE AGENT: Optional phase 2 tools on agent-task: notes_search, notes_get, notes_capture Do not grant blind outline/delete without policy.

PRINCIPLE: Adding a notes feature = adding Nopales functions. Remote agents gain them automatically through eval.

personal-garden

Garden notes are personal content – not system/main; path+author isolation
[status: implemented]

– *agent note:* 2026-08-02: tree_store garden root data.note.u.<user>; notes/garden-root ? tree/garden-root; notes/* list scoped via tree index not system/main seed.

[verify] smoke: notes created while on <user>/personal land under data.note.u.<user>; smoke: notes/ list default scope is current user garden only; smoke: pp-sync snapshot/pull never writes garden note bodies into libs/; smoke: system/main checkout does not seed or clobber garden notes*

CODE vs CONTENT: notes/* roam/* outline/* packages may live on and promote to system/main (shared product code). Note *bodies*, folders, heading trees, note-link edges for the garden MUST NOT be treated as package defaults and MUST NOT be seeded from libs/*.

WHY NOT "data branch" literally (v1): branching.data and one-tree placement A keep /data shared (no branch_id). Full per-lens versioned data is placement B and deferred. Garden isolation v1 is: 1. path prefix data.note.u.<username>.? 2. author = session user on write 3. notes/* list/get/search default to that prefix 4. never promote note rows via package seed/reseed That meets "none of these notes live in main" as product content without breaking shared bible/todo data. (* agent note (|2026-08-23 MAKE: data lens namespace (data.l.<lens>.<user>.<type>.<id>) is implemented v0 – see one-tree.borg branching-interaction. The garden isolation rules (author = session user, user-scoped list/get, never seed) are unchanged. Notes' legacy path grammar (data.note.u.<user>.?, type-before-user, confirmed live on prod 2026-08-23) migrates to data.u.<user>.note.? as a separate make task – one migration to the final shape.|) *)

MULTI-USER: Alice does not list Bob's data.note.u.bob subtree via the default notes UI/API. Admin escape hatches are explicit.

WORK BRANCH: Humans edit garden while checked out on <user>/personal (or dev for code spikes). Content path is user-keyed, not branch-keyed, so checkout does not hide your notes.

garden-import

One-shot Obsidian/markdown vault import into the personal garden tree
[status: partial]

– *agent note:* 2026-08-02: scripts/import_obsidian_notes.py dry-run+apply, bible:[[?]]?sexp, garden/ folder prefix, collision slugify. Still missing pass-2 uuid note-link reindex after upsert (verify smoke).

[verify] smoke: dry-run on vault root reports md/folder/link counts; zero writes; smoke: apply imports md under data.note.u.<user>.garden.?; smoke: headings become heading nodes; frontmatter title/org_id kept; smoke: [[wiki]] resolved to uuid edges in pass 2; smoke: [[bible:?]] normalized to (bible ?) sexps; smoke: skip EXPORT, .obsidian, tex/pdf/video/aux; smoke: re-import same source_path/org_id updates in place

SOURCE (example): /home/roerick/obsidian_vault ~227 md files; also tex/pdf/EXPORT/video – not imported.

SKIP: .obsidian/**, EXPORT/**, templates/** (optional later), *.{tex,aux,log,pdf,mp4,webm,mov,pyc,png,base}

ROOT PREFIX: data.note.u.<user>.garden.<vault-relative folders?>.<slug> Keeps import namespace clear of native PP wiki paths; refile later is tree/move.

DISPLAY: The garden/ prefix is an import namespace, not a user- facing folder. The /notes index STRIPS a leading garden/ so imported contents appear at top level as siblings of native folders (roam, reading, history as top-level folders; no garden bucket in the UI).

FILE MAP: directory -> folder nodes (title = dir name) file.md -> note leaf slug <- filename stem sanitized [a-z0-9-]+ title <- yaml title | first H1 | stem source_id <- yaml org_id if present source_path <- vault-relative path (re-import key) tags <- yaml tags kind/day <- Diary/YYYY-MM-DD.md => daily + day # / ## / ? -> heading spine; preamble = root body body markdown -> heading body text (light normalize)

LINKS (two-pass): Pass 1: create folders + notes + headings (no edges). Pass 2: scan bodies for [[?]] and bible forms; write uuid edges; normalize bible: Obsidian links to sexps.

SLUG COLLISIONS: Global per-user uniqueness. On clash, prefix with parent folder label or numeric suffix; report in import log.

TOOLING: Offline importer (OCaml CLI or pp-eval batch driver). –dry-run required before apply. Not an image hot path. Idempotent on source_id/source_path.

NON-GOALS: Continuous sync, tex pipeline, quartz theme fidelity, dataview, round-trip export to the vault.

tree-cutover

Phased delivery: kernel tree prims ? fa?ade ? UUID links ? M0 PP migrate ? M1 vault

[status: partial]

> – *agent note:* 2026-08-02 confirm: K0-N1/M0/I* largely done (index-read-path implemented). Open: M1 pass-2 links, F finish-cutover slices (legacy light/* residue, heading explode polish, legacy row delete).
>
> *[verify] smoke: K0: tree/get list upsert delete move on folder/note/heading; smoke: K1: tree/get-uuid + slug uniqueness reject; smoke: N0: notes/doc/* round-trip on tree with heading children; smoke: N1: folders via path; no folder string field on write; smoke: R0: uuid note-link + bible sexp render; smoke: M0: existing PP notes migrated; spot-check agents + inbox; smoke: I4: notes/doc/list/row tree-only; no (rows 'note) outside migrate; smoke: GET /notes flat index lists garden/tree-only notes; smoke: tree-browser (tree/render-doc slug root depth fo) walks notes outline; smoke: M1: vault dry-run + apply on personal garden*

SLICES (one initiative, shippable checkpoints): K0 tree prims + readable note path labels K1 get-uuid + slug unique constraint/index N0 notes fa?ade on tree; outline?heading (whole-replace ok) N1 folders via path; retire folder field writes R0 UUID links + bible sexp render via bible/dabar M0 migrate data_rows note ? tree (same uuids) I* index-read-path (I1-I4): one UI/agent read path through notes/doc/* ? tree; flat /notes; light/* deleted M1 Obsidian md import (garden-import) – still open D0 docs: one-tree flag defaults truth; design note appendix

DEPENDENCY: Does NOT wait on global PP_TREE_READS=1 for all CRUD. Notes use tree_* prims directly. Flat types keep CRUD.

STATUS NOTE (post index-read-path I1-I4): K0/K1/N0/N1/M0 + I1-I4 are realized. notes/doc/list and notes/doc/row are tree-only (no data_rows fallback). Legacy type=note rows remain as inert archive; only notes/migrate/legacy-* may (rows 'note). /notes routes to notes/page ? notes/ui/folders-html (flat, budget-safe via tree/note-index). notes/list-light aliases index-list. Nested notes/tree/render retired (legacy tombstones). Remaining for full "implemented": M1 garden-import apply, R0 completeness if any bible/roam gaps, D0 docs polish.

FINISH-CUTOVER (the close-out slices): F1 Delete the legacy nested index (notes/light/*) from the image so /notes serves ONLY the flat budget-safe index over tree/note-index (I1 completion). F2 Index groups by PATH-derived folders; a leading garden/ strips to top level (garden-import DISPLAY). F3 M0 completion: explode every migrated note's inline outline blob into real heading child nodes (the Roman notes currently render as one blob with a single

heading); normalize path labels to kebab slug. F4 Delete the legacy data_rows type=note rows after F3 verifies every uuid in the tree (no archive). F5 Vault drift: pp-sync the live notes bindings back to libs/ so git matches the image before further edits.

TREE-BROWSER BACKEND SWAPS (content tree contract): image.tree-browser v1 walks the CONTENT tree – the notes outline model (outline/id title kids) rooted at a note slug – NOT tree_nodes paths. Contract that must stay stable when storage backends move: (tree/render-doc slug root-id depth folders-only?) -> html string node accessors used by the walker: outline/id, outline/title, outline/kids, outline/find + notes/doc/get ? outline (today notes/doc/outline) Swapping outline JSON-in-note for heading nodes under data.note.? MUST keep those accessors (or a thin adapter with the same names). tree/render itself does not call tree/get or rows. Store-tree roots (v2) are a different root kind and need lens-aware prims (filed separately).

RISK: Never write hierarchical notes as kind=datum. Reverse mirror only handles fn/type/route/datum.

unified-todos

Basecamp lists + org node todos; unified /todos with smart views

[status: implemented]

Real lists: todo-list + todo-item (list_id, title, notes, state, due, position). state in todo/state/list (Nopales). Note todos: outline node.todo; scrape + write-back. Smart views: everything, from-notes, default Inbox. /todos nav + body; cycle state; create list; add item. No dual-copy of note todos until promote (later).

> *[verify] smoke: /todos everything + from-notes + inbox; smoke: cycle note TODO write-back; smoke: create list and add item*

kanban

Board view over todos: one todo-list as a board with its own columns (per-list state set), cards draggable via tree actions

[status: implemented]

2026-12 campaign 9.0: flipped to implemented. BORGE-1786336755 closed - the per-list state-cycle threading is live: todo/item/cycle + todo/cycle read the item's list's OWN columns (single source of truth todo/state/columns-for-list, which falls back to todo/state/list) and the detail <select> uses list-aware todo/state/options-for-list, so a custom-columns list cycles exactly its columns in /todos, the todo detail, and /kanban alike. There are no duplicates - /todos detail and /kanban read the same function.

A kanban is a VIEW over the existing todo model, not a new data type. A board IS one todo-list; its columns ARE that list's OWN state set (a 'columns' field on the todo-list datum); its cards ARE that list's todo-items. No kanban-card type, no kanban-board type. This is the first product consumer of the tree prim family as a DATA API (one-tree.tree-datum-prims): every mutation is a tree action over a datum node (the list for column config, the cards for moves), not a create/update call.

PER-LIST COLUMNS, NOT A GLOBAL STATE LIST. The todo package ships a default state list (todo/state/list: "", TODO, DONE, WAITING, CANCELLED). A list that does not set its own 'columns' falls back to that default – so existing /todos and existing lists are unchanged. A list that sets 'columns' overrides the default for itself: the board renders exactly those columns, in that order, and a card's 'state' is one of them. This makes the todo state model per-list configurable instead of a single fixed global – the same mechanism answers "set your own columns" and "set your own todo state": edit the list's 'columns' field. (The default list stays as the fallback and the seed for new lists; it is not deleted.)

BOARD = ONE TODO-LIST. The /kanban route takes a list_id (defaults to the Inbox). A list-picker switches boards. Adding a card adds a todo-item to the list (create, the id-generating convenience); the board re-reads.

CARDS = todo-items of the list, grouped by state. Read via tree/list over data.u.<user>.todo-item.* plus a list_id filter, OR via the todo package's existing todo/items-for-list helper composed with tree/list. Each card shows title + due; click opens the existing todo detail. Cards whose ‘state‘ is not in the board's current columns render in a trailing "other" bucket so a removed/renamed column never silently hides cards.

MUTATIONS ARE TREE ACTIONS (the point of this subsection + the prerequisite one-tree fix). The list datum and each card datum are tree_nodes; every mutation is tree/get + dict-set* + tree/upsert at the same path: - MOVE CARD BETWEEN COLUMNS (drop on a state column): tree/get the card's datum node, dict-get its body, dict-set* the ‘state‘ field to the target column name and ‘position‘ to the drop index, tree/upsert the new body at the SAME path. Goes through the reverse mirror so (get 'todo-item id) and (rows 'todo-item) see the new state, exactly as if update had written it. - REORDER WITHIN A COLUMN (drop between two cards): same tree/get + dict-set* ‘position‘ per moved card; wrap the N affected cards in with-transaction so the reorder is atomic and no two cards share a position mid-drop. - ADD / REMOVE A COLUMN: tree/get the LIST datum, dict-set* its ‘columns‘ field to the new array, tree/upsert the list at the same path. Removing a column does NOT delete its cards (they land in the "other" bucket until reassigned). - RENAME A COLUMN: tree/get the list, dict-set* the new name into ‘columns‘, AND cascade – in one with-transaction, tree/upsert every card of that list whose ‘state‘ is the old name with the new name. Rename is all-or-nothing across list + cards. - No re-parenting / tree/move in v1: a card's list is a field (list_id), not a path segment, so moving a card to another board is a field update, not a path change. tree/move is available per one-tree.tree-datum-prims but unused here.

UI / HTMX SHAPE: - GET /kanban?list=<id> renders html/page with a flex row of columns. Each column is a <section> with an hx-post drop target; each card is a draggable article with a tiny dragstart/drop JS shim that encodes the dragged card id + drop position into hidden form fields, then submits the column's hx-post. Same POST-to-one-route + hx-request? partial-vs-redirect pattern as /todos. - A column header has inline add/rename/remove controls (small forms, same hx-post pattern); the board footer has an "add column" form. - POST /kanban dispatches on action: move (card to column + position), add-column, rename-column, remove-column. Each performs the tree action(s) above and returns the refreshed board partial via render-html when hx-request?, else redirects. - No JS framework, no new asset pipeline – the shim is a small <script> in the page, same style as the outline keyboard-nav script (must pass scripts- check per notes-ui-contract). - Accessibility: each card reachable by keyboard; move via a per-card up/down/left/right control as a no-DnD fallback (the DnD shim is progressive enhancement, not the only path).

RELATION TO /todos: the /todos page keeps its list/detail smart-view UX; /kanban is a sibling route over the same rows. Both read/write the same todo-item datum nodes; no duplication, no sync. Cycling state from /todos updates the kanban and vice versa because they share the store. A list with custom columns shows those same states as the /todos state cycle options for that list (the state machine reads the list's ‘columns‘ when present, else the global default).

NON-GOALS (v1): - No WIP limits, no swimlanes, no per-user assignment columns, no card cover images. - No multi-list board (board = exactly one list). - No tree/move re-parenting of cards across types. - No per-USER state set (columns live on the LIST, not the user; a user's different lists may differ).

[verify] build: dune build @all; smoke: GET /kanban?list=<inbox> ren-

ders the inbox's items grouped into columns by the list's columns (or the default state list when the list has none), empty columns included; smoke: a list with its own columns field renders exactly those columns; /todos for that list cycles only those states; smoke: drag a card to another column (POST action=move) ? the todo-item's state field changes via tree/upsert; /todos and /kanban both reflect it; smoke: add / remove / rename a column ? the list's columns field updates via tree/upsert; rename cascades to cards in one with-transaction; smoke: reorder within a column ? positions renumber atomically (with-transaction); no two cards share a position; smoke: keyboard no-DnD fallback moves a card left/right between columns

search-modal

Typeahead find modal: one server search feeds open-note and refile; flat grouped results down to header level

[status: implemented]

– *agent note:* 2026-08-02: notes/search + notes/ui/search-partial; route /partials/notes-search; live GET ?q=agents ? 200 grouped hits.

[verify] smoke: GET /partials/notes-search?q=? returns grouped result HTML (docs + header rows with ? breadcrumbs); smoke: results arrive without enumerating the garden in Nopales (filter happens in Postgres); smoke: modal opens via keyboard shortcut; arrows navigate; Enter opens chosen row; smoke: empty query and no-match queries render stable non-error markup; smoke: refile entry point uses the same typeahead; choosing a row refiles the selected node; smoke: node-targeted rows refile under that heading; doc rows refile at root

PRODUCT: One find-box is the "open note" interface AND the "refile destination" interface. Cmd/Ctrl-K opens a modal with a single input; typing shows results immediately. This subsection resolves priority-7 "search polish".

INTERACTION MODEL (locked: flat, grouped): Every keystroke requeries the server; the result list is ONE flat stream grouped under doc headings, header-level matches indented beneath their doc with a breadcrumb path: JOURNAL 2026 ? July 12 session TODO Projects ? pricklypear Arrow keys move, Enter activates. NOT a two-tier drill-down (?/? to enter docs): slower when you already know the header word, and refile wants doc+node targets in one list anyway.

RESULT ROW: (doc-slug doc-title node-id|() header-path matched-field) node-id () = doc-level hit (title/tags match). header-path = "Gran ? Parent ? Header" for tree cutover storage; pre-cutover (fields.outline JSON blob) only doc-level rows are emitted – header granularity ARRIVES WITH the tree cutover, it is not retrofitted onto the blob. matched-field lets the UI badge title vs body vs header hits.

SEARCH STRATEGY (v1 – tree-backed): Notes are tree-backed (notes/tree/enabled? #t), so the search runs over tree_nodes, NOT data_rows. It uses the tree/search-text prim (BORGE-1785605474): one Postgres ILIKE query over tree_nodes scoped to the garden root (path <@ $prefix::ltree) for note rows (title/tags/slug) plus a second query for heading rows (title/body with a ?-joined header_path breadcrumb), merged + deduped by slug in OCaml, capped (?20 rows). Empty/no-match queries return (); garden-wide Nopales enumeration is FORBIDDEN on this path (BORGE-1785603757: ~3k notes ? eager enumeration blew the 100k step budget) – filtering happens in Postgres. Prim signature: (tree/search-text needle [limit]) – garden root (tree/search-text prefix needle [limit]) – explicit path Note: data_rows find-text (fields-»f ILIKE, crud.ml) is NOT used – it would miss the tree garden. Doc-level rows carry empty node_id; header rows include header_path + node_id (refile to a header parents under that node). Ranking v1 in OCaml: exact-slug first, title hits, then header, then body.

Fuzzy/typo tolerance (pg_trgm) and ranked FTS (tsvector, cf. dabar.search-fts) are later upgrades that swap the query behind the SAME partial – the modal does not change (the prim signature is the seam). Track under .borge-bugs when demanded by use; not spec'd here.

NON-GOALS (v1): - No load-the-whole-tree-into-JS client search - No tsvector/trgm migration (see above) - No cross-type global search (notes only; a global launcher is a product-experience question, later) - No search inside archived/hidden docs unless the current notes/doc/list filter already shows them

UI / HTMX SHAPE: Follows the details-popover precedent of notes/ui/refile-modal (BORGE-1785603757) – no JS framework, no new asset pipeline. Modal is a <details> (or <dialog> if focus trapping proves needed) opened by clicking "find" or Cmd/Ctrl-K (tiny script, same style as the existing outline keyboard-nav script). Input has hx-get="/partials/notes-search" hx-trigger="input changed delay:200ms" hx-target on the results container. Arrow/Enter handling extends that script; htmx 'htmx:afterSwap' re-focuses the first result.

ROUTES (all private, current branch): GET /partials/notes-search?q=? ? grouped result HTML GET /partials/notes-search?q=?&mode=refile ? same list, rows refile the selected outline node (POST action=refile with dst_slug + optional dst_node_id) instead of navigating. Open-note activation navigates to /notes?slug=? (&node=? for header rows when the tree cutover lands).

REFILE CONVERGENCE: notes/ui/refile-modal's raw dst_slug text input gains a mode=refile typeahead against the same partial (exact slug entry keeps working – no regression for agents / keyboard-only users who know the slug). Refile to a header target parents the subtree under that node; refile to a doc row parents at root (current behavior). The existing POST /notes action=refile handler accepts an optional dst_node_id.

BUDGET INVARIANT: /notes?slug=? page render must stay O(1) in garden size: the modal ships collapsed markup only; all searching is on-demand partials. Any future caching (e.g. a per-branch doc-index value) is optional and must be invalidated conservatively; premature caching is a non-goal.

pricklypear-structural-editing

Pricklypear book chapter: structural editing – paredit-shaped tree surgery as one shared protocol over outlines and code ASTs

[status: partial]

> – *agent note:* 2026-08-02 status reconcile: structed-algebra+op-protocol+keymap+non-goals implemented; only ast-structure-view remains planned – keeps project/section partial.

structural-editing

Structural editing: named tree ops over one shared protocol – outlines and code ASTs are edited as trees, never as paren text

[status: partial]

==========

PRODUCT INTENT ==========

Programs are trees. Outlines are trees. Editing either one should be TREE SURGERY with named operations – slurp, barf, wrap, splice, raise – never character editing over a serialized rendering. This chapter defines ONE interaction protocol for structural editing, shared by the notes outline editor (notes.hypermedia-ui) and the function editor's structure view (image.function-editor), and later by any tree-shaped surface.

The paredit vocabulary (slurp / barf / wrap / splice / raise / split / join / transpose) is the headline, but the chapter is really three rules:

RULE 1 – You type inside atoms; you never type structure. contenteditable is for LEAVES (titles, bodies, atom text). Structure changes only via named commands. Unbalanced structure is unrepresentable.

RULE 2 – The server is authoritative for structure. The browser sends (op, target, args); the image applies a PURE function to the tree and returns a re-render plus the new selection. The client MAY apply that same pure op locally for immediate feedback via the browser evaluator (client-eval) – the result is COMPUTED by the same source the server runs, not predicted from a divergent client codebase – and reconciles to server truth by morph on response. What is forbidden is structural prediction from a SECOND, hand-maintained client implementation of the op algebra (the lie).

RULE 3 – Selection is part of the op algebra. Every op returns (tree', selection'): where the cursor lands after delete/slurp/wrap is computed by the same pure function that computed the tree, and travels back with the response.

STORAGE IS UNCHANGED. Outlines stay JSON strings in data_rows; function bodies stay JSONB in function_defs. The unification is the value model (nested lists/atoms) and the op protocol – NOT a storage codec migration. Whole-document write remains the conflict domain.

==========

SUBSECTIONS ==========

structed-algebra – pure higher-order op library op-protocol – the POST contract + selection OOB keymap – chords now, modal target ast-structure-view – /edit Text|Structure toggle client-eval – browser evaluator: same code, optimistic execution non-goals – what this chapter refuses to build

structed-algebra

Pure higher-order tree-surgery library (structed) usable from REPL, routes, and agents

[status: implemented]

PACKAGE: structed/ (Nopales – pure, no DB, no I/O). Load: (load-library "structed").

HIGHER-ORDER OVER CHILD ACCESS. One op implementation serves any tree whose domain supplies child accessors:

(structed/slurp-forward get-kids set-kids tree target)

The outline backend passes (outline/kids, outline/set-kids); the AST backend passes expr-children accessors. Do NOT duplicate op logic per domain, and do NOT force one node shape across domains.

OP SET (v1): slurp-forward target absorbs its next sibling as new last child slurp-backward target absorbs its prev sibling as new first child barf-forward target's last child becomes its next sibling barf-backward target's first child becomes its prev sibling wrap target becomes sole child of a fresh node (fresh-node shape is domain-supplied; the expr domain takes an optional head-atom arg: (wrap t "f") on x -> (f x), so wrapping never needs an empty head – see ast-structure-view) splice target removed; its children take its place, in order raise target replaces its parent split target divides at a position into two adjacent siblings join target merges with its next sibling transpose target swaps with an adjacent sibling The existing outline ops promote / demote / move-up / move-down are the outline-domain special cases of this vocabulary and stay where they are.

TOTALITY: every op is total. Unknown target, missing sibling, root-guard violation, wrong shape -> identity tree and UNCHANGED selection. A structure key must never produce an error page.

RETURN SHAPE: (list tree' selection'). Selection rules: slurp / barf / wrap / transpose : selection stays on target splice : first lifted child, else parent raise : stays on target (now at parent's place) delete (domain op) : next sibling, else prev, else parent add-child / add-sibling : the new node

PROPERTIES TO TEST (Nopales-level via load-string + eval; no services, no browser): slurp-forward then barf-forward = identity on the tree wrap then splice = identity on the tree any op on empty / atom / unknown target = identity

> *[verify] smoke: (load-library "structed") exposes structed/*; smoke: slurp+barf and wrap+splice round-trip to identity on a sample tree; smoke: ops against root/unknown/empty targets return input unchanged*

op-protocol

One POST contract: (op, target, args) -> re-render + out-of-band selection

[status: implemented]

WIRE: structure edits and leaf edits are the same protocol.

POST {op, target, field args...} -> 200 HTML: re-rendered tree fragment (outerHTML swap) + out-of-band selection state (hidden element swapped via hx-swap-oob carrying the new selection address).

The client shell restores highlight + caret after each swap. This extends the notes/outline/apply-op pattern: dispatch by op name to a pure fn; unknown op -> (tree, same selection), still a 200 re-render.

SURGICAL WIRE, WHOLE-DOC STORAGE. Payloads name a node and small args – never the whole document. The server decodes the whole tree, applies the pure op, encodes, writes the whole document (data_rows field or function_defs body). The DOCUMENT is the conflict domain; no per-node storage in v1.

ABSTRACT TARGET IDENTITY. Outline surfaces address nodes by stable id (already true). The AST surface addresses nodes by PATH (data-path="0.2.1") until branching.ast-nodes provides stable node ids. Op responses always return the selection's CURRENT address, so path invalidation after reorder is handled by construction. Upgrading identity (paths -> ids) must not change the protocol or the client.

RESPONSIVENESS VIA SAME-CODE EXECUTION. The client runs the same pure op locally through the browser evaluator (client-eval) for immediate

feedback, then the server confirms authoritatively and the response is MORPHED in – never merged field-by-field with the prediction, never patching client state. Because the local result is computed by identical source, the divergence window is server-only effects (validation, concurrency), not code drift; an opseq guards staleness so an out-of-order response cannot clobber a newer local state. The htmx-org hx-optimistic extension (template placeholder, swapped wholesale on response) remains available for non-structural previews but is not the structural mechanism. The client shell may ignore structure keys while one op POST is in flight (single-flight), and restores selection + focus from the OOB payload on completion.

FLUSH RULE. Any structure POST first flushes the focused leaf's pending edit (set-title / set-body / set-atom) – either folded into the same request or as a forced blur-commit – so a tree re-render can never destroy in-progress leaf text. This replaces any narrower "commit on blur" rule.

UNDO. Whole-tree snapshots per op are the undo model – trees are persistent values, snapshots are cheap. Ring placement (client or server session) is v1 implementation discretion.

> *[verify] smoke: POST outline op returns tree partial + OOB selection element; smoke: delete selects next sibling; at end of siblings selects parent; smoke: unknown op name re-renders unchanged tree with 200*

keymap

Chord-first keyboard map; modal structure/text interaction is the documented target

[status: implemented]

> – *agent note:* 2026-08-02: v1 Alt chords shipped in notes outline script (libs/notes/lib.pp): Alt+Up/Down move, Alt+Shift+Left/Right promote/demote, Alt+Left/Right barf/slurp, Alt+Enter sibling; preventDefault. Modal map still documented target not v1.

V1 – MODIFIER CHORDS ONLY. Plain keys always edit text when a caret sits inside a contenteditable leaf; structure never fires on an unmodified key. Required chord set (outline surface; AST surface mirrors):

Alt+ArrowUp / Alt+ArrowDown transpose with prev / next sibling Alt+Shift+ArrowLeft / Right promote / demote Alt+ArrowRight slurp-forward Alt+ArrowLeft barf-forward Alt+Enter add sibling

The full op set stays reachable via toolbar/menu. No structure key fires during IME composition.

CHORD CONFLICT (known – verify early). Alt+ArrowLeft / Alt+ArrowRight is browser history back/forward on Linux and Windows. The map relies on preventDefault winning when the editor has focus: VERIFY THIS FIRST in the keymap work, in the target browsers, before building more on it. If preventDefault does not hold, slurp/barf move to Alt+Shift+ArrowLeft/Right and promote/demote relocate (e.g. Alt+, / Alt+.) – update the table then. Do not add per-OS keymaps in v1.

TARGET – MODAL (not v1 acceptance): a structure mode (a whole node is selected; plain keys move selection and operate; Enter enters the title as text) and a text mode (caret in leaf; Esc returns to structure mode). Server and protocol are mode-agnostic – modal is a pure client evolution. Client code MUST keep a distinct keymap layer (a data-driven chord table, not scattered hard-coded checks) so the modal map can replace the chord map without touching op dispatch.

ONE CLIENT SHELL. Selection state, postOp, blur-commit, restore-after-swap, and the keymap layer are ONE script pattern shared by the outline editor and the AST structure view – generalized from the notes outline script, not forked per surface.

> *[verify] smoke: Alt+ArrowRight on a selected node slurps its next sibling; smoke: Alt+ArrowLeft/Right never trigger browser history navigation while the editor is focused; smoke: plain keys with caret inside a leaf edit text only; smoke: structure op in flight: second chord ignored; selection restored after swap*

ast-structure-view

Function editor gains a Text | Structure toggle over the same function_defs row

[status: planned]

> – *agent note:* 2026-08-02 confirm still planned: no Text|Structure toggle on /edit/<name>; function editor remains textarea. structed algebra + outline op-protocol ready as substrate.

/edit/<name> gains a view toggle: Text (existing textarea, parse whole body on save) | Structure (AST rendered as addressable nested HTML – the outline/html-node ADDRESSING pattern (data-path on every node) applied to exprs, NOT the outline's row layout). Lists are structural containers; atoms are contenteditable leaves.

LAYOUT IS A PRETTY-PRINT, NOT AN OUTLINE. The structure view must NOT render one node per line – that would make (+ 1 2) taller than it is wide and code unreadable. The renderer is a pretty-printer over the AST: - atoms, and lists that fit within a width budget, render INLINE on one line: (+ 1 2), (dict-get u "name") - a list breaks vertical only when over budget, or by form-aware convention (define / lambda / let / cond bodies one form per line; operator applications stay horizontal while they fit) - vertical children indent by depth; all whitespace is derived, never stored – the AST carries no layout bytes Selection and data-path addressing are layout-independent: a node keeps the same path whether its children flow horizontally or vertically, and structural ops behave identically either way. Layout direction is a per-domain RENDER decision – outlines render one node per row because that IS the outline reading experience; code renders as a pretty-print. The shared op protocol does not care.

BUILD ORDER (layout): 1. VERTICAL RENDERER FIRST: every list breaks vertical, one node per line – the degenerate pretty-printer (width budget zero). Easiest correct render, and it exercises the hard parts (data-path addressing, selection restore, ops, atom edits, re-render) before any layout engineering. NOT a throwaway: because addressing and ops are layout-independent, stage 2 changes only the renderer. 2. INLINE PACKING: introduce the width budget and form-aware conventions; short forms collapse onto one line. Pure renderer change – protocol, ops, paths, and the client shell are untouched.

BACKEND: the same structed algebra with expr accessors. The AST is an expr tree (App / Lambda / Let / If / Quote ...), NOT a tree of VLists: child access is defined PER CONSTRUCTOR as the subexpressions in reader/surface order (App -> head then args; Lambda -> params then body; If -> test, then-branch, else-branch). Quoted literals are OPAQUE LEAVES in v1 – no descending into quoted data. The exact per-constructor child table is implementation discretion within that constraint. Domain differences: wrap takes an optional head-atom – (wrap t "f") on x -> (f x); with no arg it wraps in a fresh one-element list. split/join operate on list element runs; there is no promote/demote – raise/splice cover that space.

ATOM EDITS ARE TRANSACTIONAL AND TYPE-AWARE. The renderer tags each leaf with its atom type. Blur sends set-atom {path, text}; the server validates PER TYPE: - string leaves: text is accepted RAW – spaces and parens are data, not syntax - symbol / number / bool leaves: text must read-string as exactly one atom of a compatible shape, else the old value is kept and the tree re-renders unchanged - converting a leaf's TYPE (symbol ->

string, number -> symbol) is an explicit op, never a side effect of editing text Because invalid text never enters the AST, HOLES are not needed in v1; a hole node type is a possible later extension, deliberately out of scope here.

SAVE IS UNCHANGED: whole function body, JSONB, via the existing value<->JSON codec and the function_defs row. The structure view is a second editor over the same storage – not a new persistence path.

AI AUTHORING: op + path + args with whole-body write is the surgical patch surface ai-authoring asks for, ahead of branching.ast-nodes. When ast-nodes lands, paths upgrade to stable ids behind the same protocol (see op-protocol abstract identity).

> *[verify] smoke: GET /edit/<fn> structure view renders nested tree with data-path leaves; smoke: layout stage 2: a short form like (+ 1 2) renders on ONE line, not one node per line; smoke: layout stage 2: define/lambda body breaks vertical by convention; selection paths stable across both layouts; smoke: set-atom with unparseable text keeps old value and re-renders; smoke: set-atom on a string leaf accepts raw text containing spaces and parens; smoke: slurp via POST re-renders; saved body reflects the change on reload*

client-eval

Browser build of the Nopales evaluator runs the same pure op algebra the server runs, so an optimistic edit is a real local computation – not a predicted guess – reconciled to server truth by morph

[status: implemented]

SAME EVALUATOR, SECOND TARGET. The pure interpreter core (lisp/lib: reader + ast + eval + env, no I/O) is compiled to JavaScript via js_of_ocaml. OCaml 5 effects require the CPS backend: every JS build passes –effects=cps, or it fatally aborts. The same .pp package source the server serves is evaluated verbatim in the browser – structed, outline, html ride along as data, never reimplemented.

SAME SOURCE AT RUNTIME, not at build. The browser fetches the current branch's package source on page load (the image is the API) and evaluates it, so a user who redefines structed/barf-forward on their personal branch has their browser run their version. Build-embedded source is a boot fallback only – it would drift the moment a promote lands without a redeploy, breaking the branching chapter's live-source invariant.

PURE PRIM TABLE ONLY. The browser prim table registers the pure prims and EXCLUDES every DB / IO / net prim. The pure/DB split already exists in code (prims_pure.ml vs prims_db.ml); this subsection makes it structural – prims_pure is factored into a library both image/ and client/ depend on, so the two runtimes cannot drift on what "pure" means. Each registered prim name is bound as VPrim in the browser env, mirroring session.ml's auto-bind loop, so (list ...), structed/*, outline/* resolve. The capability boundary IS the prim table: a structed op cannot touch Postgres because those prims are simply unbound.

OPTIMISTIC EXECUTION MODEL. On a structure op: 1. client applies the same pure op fn to its local tree 2. renders via the same render lib (libs/html / outline) 3. morphs the result into the DOM with a pp-in-transit class on the affected subtree (grey = unconfirmed, the chat-app sending/sent indicator – never a claim of truth) 4. fires the real POST carrying an op-seq 5. server: stale seq -> 409, client morphs server truth back; else persist + return server-rendered fragment 6. client morphs the fragment in; class clears. If the two renders agree (same code, deterministic) the morph is a no-op except grey -> normal. error -> toast + morph to server truth.

OP-SEQ. A monotonic sequence per editing session travels with each op; the server rejects out-of-order ops so a late response cannot clobber a newer local state. Single-user edits serialize naturally. Multi-user concurrency is

unchanged from op-protocol: the document is the conflict domain, last-write-wins on whole-doc save.

WHY THIS IS NOT THE LIE. The objection to optimistic updates (optimistic updates are a rendering trick pretending to be application truth) lands when the optimistic result is a GUESS from a second codebase. Here the local result is produced by the SAME evaluator running the SAME source; the only divergence sources left are server-only effects (validation, uniqueness, concurrent writers) – exactly what the op-seq + morph + toast path exists to surface. There is no second implementation to drift.

CONFORMANCE IS THE GATE. The lisp conformance suite (lisp/test/conformance_test.ml) runs against the JS target, so client/server agreement is a tested invariant, not a hope. The client-eval subsection is not accepted until that gate is green.

NOT A REPLACEMENT FOR THE PROTOCOL. The op-protocol POST contract, OOB selection, flush rule, and single-flight shell are unchanged. client-eval only changes what the client does BETWEEN keypress and response: compute locally with the same code, instead of showing a static placeholder.

> *[verify] build: dune build client/ yields interp.js; js_of_ocaml invoked with –effects=cps; test: browser evaluator passes lisp/test/conformance_test.ml against the JS target; smoke: page load fetches current-branch structed/outline/html source and evaluates it without error; smoke: op click: local apply renders grey; server confirm morphs and clears grey; matching renders make the morph a no-op; smoke: stale op-seq: server 409, client morphs server truth back; smoke: op error: toast shown and DOM morphed to server truth*

non-goals

What this chapter deliberately does not build

[status: implemented]

- NO paredit-over-text: no paren surgery inside a textarea or CodeMirror buffer. The tree is the editor; text buffers remain for the Text view and /code browsing. - NO one-node-per-line as the FINAL code layout: vertical rendering is build stage 1 (degenerate pretty-printer), not the accepted end state – the end state is inline flow with width/convention breaks (ast-structure-view). - NO structural prediction from a DIVERGENT client codebase (op-protocol). Same-evaluator local execution (client-eval) is sanctioned because the result is computed by identical source, not guessed; what remains forbidden is a second, hand-maintained client implementation of the op algebra. Display-placeholder optimism via the hx-optimistic extension stays allowed for non-structural previews the response replaces wholesale. - NO storage codec migration: outlines stay JSON strings in data_rows; code ASTs stay JSONB in function_defs. A canonical sexp writer prim (write-string) for agent-facing output may be added independently under lisp-interpreter.primitives; this chapter does not depend on it. - NO per-node storage and NO multi-user concurrent node editing: the document is the conflict domain. - Modal keymap is the documented target, not v1 acceptance (keymap). - Hole AST nodes (ast-structure-view). - SINGLE-NODE SELECTION ONLY in v1: no ranges, no multi-select, no region ops. - KILL / YANK (subtree cut-copy-paste, ideally as sexp text on the system clipboard) is deferred, not ruled out – it is how larger code moves will work later. - STALE WRITES: whole-document save makes two tabs on one document last-write-wins in v1. This inherits image.function-editor's deferred optimistic- concurrency / stale-body-reject item; resolve both together.

> – *agent note:* 2026-08-02: documentation-only; implemented as spec-complete.

21 borge/calendar.borg

pricklypear-calendar

Pricklypear book chapter: calendar
[status: implemented]

– *agent note:* 2026-08-02 status reconcile: sole child model already implemented; libs/calendar/lib.pp ~802 lines; live calendar/today + 27 events; GET /calendar 200.

calendar

Month/day calendar: events + due todos + daily notes
[status: implemented]

model

Naive local dates; shared data_rows; Nopales package
[status: implemented]
A calendar should load fast and stay out of the way: month grid + day agenda is enough to plan a week, and naive local dates keep the model honest (no timezone UI pretending to be correct).
CHOICES (v1): - Day click opens day agenda (not auto-create) - Naive local YYYY-MM-DD (no TZ UI) - Seeded on boot after todo - Month + day only (no week view yet)
DATA: calendar-event title day start_time end_time all_day notes location color source
OVERLAYS (read): todo-item.due on day notes daily-YYYY-MM-DD presence
PRIMS: date-today date-weekday date-format
ROUTES: /calendar ?ym= ?day= Package: calendar/*

[verify] smoke: GET /calendar shows month grid; smoke: GET /calendar?day= shows agenda + add form; smoke: create event appears on day

22 borge/flashcards.borg

pricklypear-flashcards

Pricklypear book chapter: flashcards – decks + spaced-repetition cards as Nopales + data_rows

[status: implemented]

flashcards

Decks, cards, study queue, FSRS-4.5 review, hypermedia UI, agent API

[status: implemented]

> *[verify] build: dune build image; smoke: (load-library "flashcards") installs flash/? and routes; smoke: GET /flashcards lists decks; create deck appears; smoke: add card to deck; GET deck page lists it; smoke: GET /flashcards/study?deck=? shows due card front; reveal + rate; smoke: rate again/hard/good/easy updates due + stability; card leaves or re-enters queue; smoke: pp_eval '(flash/due)' returns due cards for agents; smoke: seed_stdlib loads flashcards after calendar (or documented order)*

========== PRODUCT INTENT ==========

A first-class memorization app on the live image, inspired by: - Anki: decks, front/back cards, spaced review grades - SuperMemo/FSRS: stability + difficulty + due, scheduled by algorithm - Pricklypear: objects in Postgres, UI as Nopales routes, agents study/create via eval – no parallel REST API

NOT a port of Anki desktop. NOT file-backed .apkg as the authority (import may come later). NOT OCaml system pages – this is a product package (Nopales).

Killer property: flashcards are Nopales values; agents and humans use the same functions.

========== LAYERING ==========

- libs/flashcards/lib.pp – package flash/? (seed on system/main) - data_rows types – flash-deck, flash-card (shared) - Routes via (route ?) – /flashcards and study/edit paths - Optional nav entry – ui/menu pin or seed menu link - OCaml – only existing CRUD/date prims; no new kernel prims required for v1 if date-today (calendar) or string due compares suffice

========== DATA MODEL (v1) ==========

Types (deftype on load; fields are documentation + form UI):

flash-deck title string description string color string (optional CSS token / hex) archived "true" | "" (hide from default list)

flash-card deck_id uuid string of flash-deck front string (prompt) back string (answer) tags string (comma-separated free text v1) suspended "true" | "" (excluded from study) ;; FSRS-4.5 scheduling state (all strings in jsonb v1): stability string float default "0" difficulty string float default "0" interval string int days default "0" reps string int default "0" lapses string int default "0" due string YYYY-MM-DD (empty or past => due now) last_reviewed string YYYY-MM-DD or empty created string YYYY-MM-DD optional

NO separate flashcard-review log table in v1 (history deferred). NO cloze / image occlusion / media blobs in v1. NO per-user row ACL – data_rows are shared (existing rule). Multi-user isolation of card content is a later multi-user.permissions concern, not this chapter's first cut.

Orphan cards (missing deck_id) show under an "(orphan)" virtual deck in the UI; agents can reassign.

========== SRS ALGORITHM (v1 – FSRS-4.5 via kernel prim) ==========

Ratings (buttons + flash/review rating arg): again | hard | good | easy

State on each card: stability (float ? 0), difficulty (float ? 0), interval (int days), reps (int), lapses (int), due (YYYY-MM-DD).

On review with rating R, today = date-today: again: reps = 0; lapses += 1; interval = 0; due = today stability = max(0, stability - 0.2) hard: interval = max(1, floor(interval * 1.2)) stability = max(0, stability - 0.15) reps += 1; due = today + interval good: if reps = 0 then interval = 1 else if reps = 1 then interval = 6 else interval = floor(interval * stability) reps += 1; due = today + interval easy: if reps = 0 then interval = 4 else interval = floor(interval * (stability + 1)) stability = stability + 0.15 reps += 1; due = today + interval

New cards: due empty or due <= today, reps=0 ? introduce in study. Suspended cards never enter the queue. Order: due ASC, then session-freshness (last_reviewed < today or blank, before last_reviewed == today), then created/id; so a card rated Again – due today, last_reviewed today – sinks to the bottom of the current stack and is not re-shown until the rest of the due batch is cleared. Limit batch (default 20) per study page.

The core scheduling is delegated to the kernel prim (fsrs-schedule stability difficulty elapsed rating) which returns (stability' difficulty' interval_days). See libs/flashcards/lib.pp flash/apply-rating for the thin Nopales wrapper.

Date math: reuse calendar/image date prims if present (date-today, and a day-add helper). If day-add is missing, file issue / add a small flash/add-days using existing prims only – do NOT invent a second calendar system.

========== PACKAGE API (flash/ prefix) ==========

Decks: (flash/decks) -> list of (id . fields) (flash/deck id) -> fields | () (flash/deck-create title [description]) -> id (flash/deck-update id fields-or-keys?) (flash/deck-archive id)

Cards: (flash/cards deck-id [limit]) -> list (flash/card id) -> fields | () (flash/add deck-id front back [tags]) -> id (flash/update id ?) (flash/suspend id) / (flash/unsuspend id) (flash/delete id) ; hard delete v1 OK (confirm in UI)

Study: (flash/today) -> "YYYY-MM-DD" (flash/due [deck-id] [limit]) -> due cards (not suspended) (flash/review id rating) -> updated fields | error string rating in again|hard|good|easy (flash/stats [deck-id]) -> simple counts (due, new, learning, suspended) as printable structure (flash/explain front back) -> explanation text from the LLM Ask the LLM to explain a card the user doesn't understand. Uses agent-session-new with a tutor seed (no tools); returns the model's text. Wrapped in an escaped HTML div by the route.

HTML / routes (handlers are flash/?-page functions): (flash/install) or load-side effects: (route "/flashcards" "flash/home-page") (route "/flashcards/deck" "flash/deck-page") (route "/flashcards/study" "flash/study-page") (route "/flashcards/explain" "flash/explain-page") (route "/flashcards/card" "flash/card-edit-page") ; optional Exact query keys are implementation discretion; document in lib.pp header. Prefer ?deck=uuid & ?id=uuid.

Naming: package directory libs/flashcards/, binding prefix flash/ (short, like todo/). Types flash-deck / flash-card (not flashcards-deck).

========== HYPERMEDIA UI ==========

/flashcards - list decks with due counts - form: new deck (title) - link to study-all (due across decks) optional

/flashcards/deck?id= - deck title, description - card table (front truncated, due, stability) - add card form (front, back, tags) - Study this deck

/flashcards/study?deck= (deck optional = all) - if no due: empty state + links - else one card: show FRONT [Reveal] ? show BACK + rating buttons - POST rating ? flash/review ? redirect next due - plain form POST (same as todos); htmx partials optional polish

/flashcards/explain?id= (htmx GET, returns an HTML div) - reads the card front+back, asks the LLM to explain it in plain language, returns an escaped with the explanation. - On the study card (after reveal), an Explain button does an htmx GET to this route; the response swaps into a

#flash-explain div below the card. A htmx-indicator span shows Thinking? during the request. No tools on the LLM session; no image context needed.

Mobile-first: big rating buttons, minimal chrome noise.

Use existing product theme classes (card, btn, table). No new OCaml CSS. Optional small flash-local classes in ui/theme later.

========== SEED / NAV ==========

- seed_stdlib: load-library "flashcards" after calendar (or after todo – order free as long as std/html exists) - recipe optional: (load-library "flashcards") from home - ui/menu: add Flashcards ? /flashcards on system seed when easy; personal may pin. Not a kernel nav hard-code.

========== AGENT ACCESS ==========

Image is the API: python3 scripts/pp_eval.py '(load-library "flashcards")' python3 scripts/pp_eval.py '(flash/add deck-id "Q" "A")' python3 scripts/pp_eval.py '(flash/due)' python3 scripts/pp_eval.py '(flash/review id "good")' No flash-specific REST. Bulk import via agent loop over flash/add.

========== NON-GOALS (v1) ==========

- Anki .apkg import/export - Cloze deletions, image occlusion, audio - FSRS / full SM-18 - Review history graph / heatmap (nice later) - Shared multiplayer decks / permissions - Sync protocol beyond data_rows + pp_sync package export - OCaml system pages for study (package owns UX) - Branch-scoped cards (data is shared by design)

23 borge/workout.borg

pricklypear-workout

Pricklypear book chapter: workout journal – fluid program documents + standardized journal facts

[status: implemented]

> – *agent note:* 2026-08-02 status reconcile: libs/workout/lib.pp (~2.6k lines) seeded; live (workout/programs) => free/ksk1/ksk2/ksk3; session-list/volume/home-page present. All chapter subsections match shipped package.

workout

Training journal: programs as fluid trees, sessions/exercises as queryable facts, plan/run/capture packages

[status: implemented]

> *[verify] build: dune build image; smoke: (load-library "workout") installs workout/? bindings and routes; smoke: GET /workout lists recent sessions + start controls; smoke: start free or program session creates workout-session in_progress with doc; smoke: log exercise facts on a session; volume query returns totals; smoke: complete session sets state complete and keeps exercise rows; smoke: resume in_progress session restores doc progress; smoke: pp_eval workout/session-list and workout/volume work for agents; smoke: seed_stdlib can load workout after calendar (or documented order)*

========== PRODUCT INTENT ==========

A first-class training journal on the live image.

Domain tension (the whole design): - Workouts / programs are extremely fluid (ladders, intervals, dice, unilateral switches, freestyle blocks, rest schemes). - Journal analytics must stay boring and queryable (volume by exercise+load over a date range, streak of days trained, what I did last Tuesday).

Resolution: hybrid model, two layers deliberately: 1. FLUID DOCUMENT – sexp/json tree for program structure and live run state. JSON and sexps are the same tree algebra; storage print form is an implementation detail. 2. JOURNAL FACTS – standardized workout-session + workout-exercise data_rows projected from the document (and/or quick-log UI) for history queries.

Inspired by: - paper training logs (date, work done, notes) - Simple program runners (KSK, Q&D, custom blocks) - Pricklypear: objects in Postgres, UI as Nopales routes, agents log/query via eval – no parallel REST API

NOT a social fitness network. NOT a wearable/HR integration platform. NOT an OCaml system page – this is a product package (Nopales). NOT a pure document store (that fails volume queries). NOT a fully normalized interval/rung schema (that fails fluidity).

Killer property: the same capture functions humans hit from /workout are what agents call via pp_eval.

Prior design note (habitat, design-paused 2026-07-18) is superseded by this chapter as authority. Keep the habitat note as a pointer / human-readable mirror, not a second source of truth.

========== LAYERING ==========

- libs/workout/lib.pp – package workout/? (seed on system/main) - data_rows types – workout-session, workout-exercise - Routes via (route ?) – /workout and session/run paths - Optional nav entry – ui/menu pin or seed menu link

- OCaml – existing CRUD/date/random prims only; no new kernel prims required for v1

Programs are CODE (+ optional doc templates), not table rows: each structured program owns a plan / run / capture triplet. Free-form sessions still use the same journal types.

==========

THREE MODELS CONSIDERED (and the choice) ==========

M1. Pure document One sexp/json object is the whole workout (plan + results). Good fluidity; bad cross-session volume queries unless every consumer understands every dialect.

M2. Pure tables workouts + exercises [+ sets] only. Good queries; bad fit for ladders/intervals/emoms/dice and program-specific structure (wide nullable columns forever).

M3. Hybrid (CHOSEN) Fluid document for prescription + live run state; standardized session + exercise fact rows for the journal; capture projects document ? facts. Programs may be weird. Facts answer a closed question set.

==========

JOURNAL QUESTIONS (closed fact schema derives from these) ==========

- Which days did I train? - Which program / intensity? - How much volume of exercise X (optionally at load Y) in range Z? - What is the history of a single session? - Did I finish, abandon, or leave in progress? - What notes / how did it feel?

Anything not required by those questions stays inside the fluid document (rungs, intervals, dice, rest schemes, UI cursor).

==========

DATA MODEL (v1) ==========

Types (deftype on load; fields are documentation + form UI). Each row is ONE tree (JSON object in data_rows.fields). Nested program variance lives under doc/params/progress/detail – never new top-level columns per program.

workout-session date string YYYY-MM-DD program string ; "ksk" | "qd" | "free" | ? intensity string ; "easy" | "medium" | "hard" | "" ; (NOT named "type" – overloaded elsewhere) state string ; in_progress | complete | abandoned notes string doc string ; JSON/sexp-print of the fluid workout ; tree (plan + live progress). Source of ; structural truth for resume/replay. duration_sec string int optional author string optional ; whoami at create; v1 may be "" ; (data_rows still shared)

workout-exercise ; QUERY GRAIN – projected journal facts session_id uuid string of workout-session exercise string ; canonical name, e.g. "Snatch L", "Swing" weight string number ; "" if bodyweight / unset unit string ; "kg" | "lb" | "" (normalize in capture) reps string int ; TOTAL completed reps (not per-set) notes string detail string optional JSON/sexp-print tree for per-set or program-specific breakdown when a program chooses to keep it

NO per-set fact table in v1. NO side column – unilateral work uses naming ("Snatch L" / "Snatch R") so aggregation stays a simple group-by on exercise name. NO separate "program definitions" table – programs are code (and templates inside plan functions / doc skeletons). NO per-user row ACL – data_rows are shared (existing habitat rule). Multi-user content isolation is multi-user.permissions later. Orphan exercise rows (missing session) show under a virtual "(orphan)" bucket in UI; agents can repair.

Field print form: On-row storage may be JSON (current data_rows convention). Conceptually every nested value is a sexp tree. Package helpers MUST hide hand-built JSON strings from call sites (workout/session-fields, workout/exercise-fields, dict-set*).

==========

FLUID DOCUMENT SHAPE (open envelope, closed top-level) ==========

session.doc is a tree. Recommended envelope (keys stable; interior free):

{ "program": "ksk", "intensity": "hard", "params": { ... program-specific knobs ... }, "progress": { ... live cursor / elapsed / side ... }, "blocks": [... free

structure: ladders, intervals, pairs ...] }

Examples (conceptual sexps; JSON equivalent is fine):

;; Kettlebell Simple & Sinister-style hard day cursor (workout-doc (program ksk) (intensity hard) (params (top-rung 5) (time-cap-min 20) (load 24 kg) (exercise Snatch)) (progress (rung 3) (side L) (elapsed-sec 740)) (blocks (ladder (rungs 1 2 3 4 5) (switch each-rung))))

;; Free session (workout-doc (program free) (blocks (pair snatch (sets 5) (reps 2) (load 24 kg)) (pair front-squat (sets 3) (reps 5) (load 60 kg)) (interval row (rounds 10) (on 30) (off 30))))

Plan generators produce docs (or doc skeletons). Run mode mutates progress inside doc (and may append detail). Capture reads doc (+ any explicit log events) and projects facts.

==========

CAPTURE PROJECTION CONTRACT ==========

Bridge rule: doc –capture–> session top-level fields + N exercise facts

Requirements: - Idempotent per session: re-running capture replaces or upserts exercise facts for that session_id; it must not double-count volume on resume/refresh. - Totals win: workout-exercise.reps is aggregate completed work. - Program-specific structure stays in session.doc (and optional exercise.detail); not exploded into new fact columns. - Canonicalize exercise names and units in capture (title case policy is package-defined; document in lib.pp). - Abandoned/in_progress sessions may already have partial facts from live writes; complete() finalizes state and may re-project.

Hybrid flavor for v1: H3 + H1 - Per-program capture functions (H3) - Structured sessions always retain full doc (H1) - Free/quick-log may build a minimal doc from facts (still store it)

==========

PROGRAM ARCHITECTURE ==========

Each structured program owns a function triplet under workout/:

(workout/<prog>-plan intensity-or-params) -> doc tree (workout/<prog>-run session-id) -> HTML (live UI) (workout/<prog>-capture session-id) -> session + facts

Day intensities are DATA inside one algorithm when structure matches (e.g. KSK easy/medium/hard = top rung + time cap params). Split functions only when day types differ structurally.

Intensity map example (package data, not tables): ksk: easy -> top-rung 3, time-cap-min 10 medium -> top-rung 4, time-cap-min 15 hard -> top-rung 5, time-cap-min 20

Macro strategy: defprogram generating plan/run/capture is DEFERRED until ~3 real programs exist (compress repetition, don't anticipate). Prefer quasiquote if/when language lands; hand-built list expansions are error-prone (see language macro feedback).

v1 programs (suggested ship order): 1. free – quick log + optional simple blocks (always first) 2. ksk – ladder / time-cap runner (proves live run + projection) 3. qd – optional second structured program (dice + aggregates) Do not block journal MVP on ksk/qd polish – free log must work alone.

==========

LIVE RUN / RESUME ==========

- Creating a structured session stores state=in_progress and doc. - Live writes: each completed rung/exercise POSTs soon so a dead browser loses little; update doc.progress and upsert facts. - Timer UI may embed a small JS widget (precedent: weather/script); server remains authority for logged work. - htmx for step transitions (complete rung ? swap next step). - Dice / random can be server-side (find-random or equivalent). - Resume: load in_progress session by id (or latest for program), re-enter run UI from doc.progress. - Cleanup: list/filter abandoned in_progress older than N days; mark abandoned via explicit UI/agent action (no silent delete).

==========

PACKAGE API (workout/ prefix) ==========
Sessions: (workout/session-list [limit]) -> list of (id . fields) (workout/session id) -> fields | () (workout/session-create program intensity [date] [doc]) -> id (workout/session-update id fields-dict) -> id | () (workout/session-complete id [notes]) -> id (workout/session-abandon id) -> id (workout/session-in-progress [program]) -> id | ()

Exercises (facts): (workout/exercises session-id) -> list (workout/exercise-log session-id exercise weight unit reps [notes] [detail]) -> id ;; upsert policy documented in lib.pp (by id or by ;; session+exercise+weight+unit for live rungs) (workout/exercise-delete id) -> id | ()

Queries: (workout/volume exercise [from-date] [to-date] [weight] [unit]) -> total reps (number) or printable structure (workout/history [from-date] [to-date] [limit]) -> sessions (workout/session-summary id) -> session + exercises structure (workout/exercise-names [limit]) -> distinct names for autocomplete

Doc helpers: (workout/doc-parse s) -> dict/tree (workout/doc-get doc key) / (workout/doc-set doc key val) (workout/project session-id) -> re-run capture for program

Programs (v1+): (workout/programs) -> list of program ids/titles available (workout/<prog>-plan ?) (workout/<prog>-run session-id) ; may be HTML page fn (workout/<prog>-capture session-id)

HTML / routes: (route "/workout" "workout/home-page") (route "/workout/session" "workout/session-page") (route "/workout/run" "workout/run-page") (route "/workout/log" "workout/log-page") ; quick log / edit facts Exact query keys implementation discretion; prefer ?id=uuid & ?program= & ?intensity=

Naming: package directory libs/workout/ binding prefix workout/ types workout-session / workout-exercise

Data functions take explicit args (safe from /api/eval). HTTP handlers are separate and thin.

==========
HYPERMEDIA UI ==========
/workout - recent sessions (date, program, intensity, state, short volume) - Start bar: program select + intensity (when applicable) + start - Continue card if in_progress exists - link to quick log (free)

/workout/session?id= - session header + notes + state actions (complete/abandon) - exercise fact table - add/edit fact row (quick correction) - if program structured and in_progress: Continue run

/workout/run?id= - program-specific live UI from doc.progress - complete-step controls POST ? update doc + facts ? swap UI - timer widget as needed

/workout/log (optional alias of free capture) - date, notes - repeatable exercise rows (name, weight, unit, reps) - save ? session complete (or in_progress if want multi-step)

Mobile-first: large tap targets during run; minimal chrome. Use existing product theme classes. No new OCaml CSS required.

==========
SEED / NAV ==========
- seed_stdlib: load-library "workout" after calendar (needs date-today; order free as long as std/html exists) - ui/menu: Workout ? /workout on system seed when easy; personal may pin. Not a kernel nav hard-code.

==========
AGENT ACCESS ==========
Image is the API: pp_eval '(load-library "workout")' pp_eval '(workout/session-create "free" "")' pp_eval '(workout/exercise-log id "Swing" "53" "lb" "75")' pp_eval '(workout/session-complete id)' pp_eval '(workout/volume "Swing" "2026-07-01" "2026-07-31")' No workout-specific REST. Bulk backfill via agent loops.

==========
NON-GOALS (v1) ==========
- Wearables, HR zones, GPS, Apple Health / Google Fit sync - Social feed, fol-

lowers, public leaderboards - Plate calculator / 1RM formulas as core (may be helpers later) - Full periodization planner / mesocycle engine - Per-set fact table / side column / equipment inventory - defprogram macro before ~3 programs exist - Branch-scoped journal rows (shared data_rows by design) - OCaml system pages for training UX - Treating JSON vs sexp print form as different product models

model

Hybrid: workout-session + workout-exercise facts; session.doc fluid tree
[status: implemented]

[verify] smoke: load-library defines workout-session and workout-exercise; smoke: session-create stores program intensity state date doc; smoke: exercise-log attaches facts to session_id with total reps; smoke: unilateral names work without a side column

document-and-capture

Fluid doc envelope + idempotent projection to exercise facts
[status: implemented]

[verify] smoke: structured session retains doc through run updates; smoke: capture/project does not double-count on second run; smoke: volume query uses facts only, not doc scraping

programs

plan/run/capture triplets; free first; ksk/qd optional structured
[status: implemented]

[verify] smoke: workout/programs lists at least free; smoke: free quick-log creates complete session + facts; smoke: optional: ksk plan returns doc with params+blocks

ui

Routes /workout, session, run, log; resume in_progress
[status: implemented]

[verify] smoke: GET /workout 200 after load-library; smoke: start + complete free session visible in recent list; smoke: in_progress shows continue entry point

agent-access

pp_eval workout/? as the API
[status: implemented]

[verify] smoke: pp_eval workout/session-list and workout/volume

24 borge/dabar.borg

pricklypear-dabar

Pricklypear book chapter: dabar – BSB study library (reader + Strong's + interlinear)

[status: partial]

> – *agent note:* 2026-08-02 status reconcile: packaging/reader/nav/strongs/interlinear/note-bible-links/work-packages/non-goals shipped; only search-fts remains partial (find-text ILIKE, not tsvector FTS). Live /dabar+/strongs 200; bible/verse John 3 16 ok.

dabar

Bible study layer on the live image: plugin libs, seeds, routes

[status: partial]

> *[verify] build: dune build image; smoke: (load-library "bible") then (bible/verse "John" 3 16) has God/world; smoke: (load-library "dabar") installs study routes without breaking /bible; smoke: GET /bible prev/next or random works after WP1; smoke: GET /strongs and (strongs/get "G26") after Strong's seed; smoke: interlinear fragment for a seeded verse after WP3*

PRODUCT: Dabar on Pricklypear is a multi-user, live Bible study environment built as *libraries* inside the user image – not a port of the Dream dabar server.

PILLARS: 1. Plugin-shaped Nopales packages (libs/*/lib.pp + load-library). 2. Canon + lexicons in Postgres data_rows (shared across branches). Personal notes/bookmarks are a SEPARATE module (not this chapter). 3. htmx partials for reading/study panels (no SPA). 4. Seeds are offline scripts; recipes only install code.

NAMING (locked): - bible/ – core reader (exists): verse, chapter, search, /bible, partials, dropdowns. - dabar/ – study layer: Strong's, interlinear, study chrome that *uses* bible/*. Do NOT rename existing bible/* without a migration plan.

RELATION TO wyo.tech/dabar: - Donor of data formats, Strong's CSV, interlinear field shapes, UX ideas (filters, prev/next, random). - That repo has no borge book; this chapter is SoT for the Pricklypear port. Link from root pricklypear.borg.

packaging

Library layout, boot policy, deps on std/bible

[status: implemented]

> *[verify] smoke: libs/bible/lib.pp loads via load-library bible; smoke: libs/dabar/lib.pp loads via load-library dabar after bible; smoke: boot seed_stdlib loads bible and dabar*

LAYOUT: libs/bible/lib.pp – reader (shipped) libs/dabar/lib.pp – study (to add) scripts/seed_bible_bsb.py scripts/seed_strongs.py (from dabar strongs.csv) scripts/seed_interlinear.py (from dabar bsb_tokens.csv)

BOOT: seed_stdlib loads: std, weather, ui, layout, welcome, ai, outline, notes, signup, todo, contacts, plan, chat, bookmarks, calendar, flashcards, bible, dabar. dabar is seeded on boot; no separate recipe step required.

DEPS: dabar assumes bible/* and html/* (std) already bound. Document in lib header; multi-file require is deferred.

INVARIANTS: - No dabar-specific OCaml except generic find/FTS if needed. - Routes under /bible stay bible-owned; /strongs and /dabar/* may be dabar-owned. - Kernel stays thin.

reader

Existing bible/ reader – baseline for dabar
[status: implemented]

> *[verify] smoke: 31086+ bible-verse rows after full seed; smoke: GET /bible?book=John&chapter=3 renders chapter; smoke: HX-Request /bible returns fragment without chrome*

BASELINE (implemented): - ref BSB:<Abbrev>:<c>:<v> - (bible/verse book ch v), (bible/chapter ?), (bible/search q) - /bible + /partials/bible-chapter - html/* selects for book/chapter/verse
- (bible/prev-ref) / (bible/next-ref) + UI - (bible/random-row) + Surprise control - empty/missing chapter UX

navigation

Prev/next chapter and random verse
[status: implemented]

> *[verify] smoke: next from John 3 ? John 4 panel; smoke: prev from Genesis 1 stays or wraps per policy; smoke: (bible/random-row) returns a ref+text; UI button works*

Use bible/chapter-counts + book ordinal (bible-book rows). Wrap policy v1: stop at ends (no wrap), or wrap OT/NT – pick stop-at-ends for clarity. Random: SQL ORDER BY random() LIMIT 1 via thin prim or store helper; exposed as (bible/random-row).

strongs

Strong's lexicon seed, lookup, pages
[status: implemented]

> *[verify] build: python3 scripts/seed_strongs.py –help exits 0; smoke: after seed: (strongs/get "H430") or G26 returns lemma/description; smoke: GET /strongs and GET /strongs?n=G26*

SOURCE: wyo.tech/dabar/src/tool/sql/strongs/strongs.csv (and dabar Schema.Strongs shape: number, lemma, xlit, pronounce, description).
TYPE: strongs-entry (or strongs) number, lemma, xlit, pronounce, description id/ref: fields.number unique (H430 / G26).
PACKAGE: prefer dabar/strongs-* or strongs/* under dabar load; public names (strongs/get) OK if namespaced carefully.
UI: /strongs list/search stub; detail by number; links from interlinear tokens.

interlinear

Word-level interlinear fragments + toggles
[status: implemented]

> *[verify] smoke: seed loads tokens for at least John 1 or full corpus; smoke: (dabar/inter "John" 1 1) returns HTML fragment; smoke: UI toggle plain vs interlinear on verse/chapter panel*

SOURCE: dabar inter_verse (bsb_sort, base_text, variant_text, translit, parsing, parsing_str, heb_str, grk_str, verse_id, heading, crossref, bsb_version).
Local file: wyo.tech/dabar build/dabar-bundle/tables/ bsb_tokens.csv (754647 token rows; reproduced by dabar-build pipeline from src/tool/sql/bsb/bsb_tables.xlsx sheet biblosinterlinear96 via extract_bsb_tables_raw.py + build_dabar_bundle.py).

STORAGE v1: per-verse JSON on a type bible-interlinear ref, tokens (JSON array of word objects), heading?, crossref? keyed by same BSB:Abbrev:C:V ref as bible-verse. ~31k per-verse rows total. Avoid millions of token rows.

RENDER DECISION (v1): pre-rendered HTML in the seeder. Token JSON stored in fields.tokens for future Nopales-side rendering; dabar/inter renders fields.html. Rendering token JSON in Nopales needs a JSON-array prim – deferred. Per-token fields kept: base_text, translit, parsing, heb_str/grk_str (per verse language), bsb_sort (order). Dropped for v1: variant_text, parsing_str, verse_id, bsb_version, footnotes/par/quote marks. Ref mapping: USFM book_identifier (gen/jhn/...) -> PP bible-book abbrev via the BOOKS table in scripts/seed_bible_bsb.py. verse_id \"John 3:16\" strings are NOT used for keying.

UI: htmx toggle on /bible chapter view and /dabar verse study; Strong's hrefs to /strongs?n=.

Full corpus seed may be large – allow –book John for dogfood. Dogfood stub (seed_interlinear_dogfood.py, John 3:16 only) is superseded by the real seeder.

(* agent note (|2026-08 recon: spec smokes said bible/interlinear or dabar/inter – actual code is dabar/inter-html; canonicalizing on dabar/inter as the alias + dabar/inter-html for the fragment renderer.|) *)

note-bible-links

Sexp bible refs in note bodies render to dabar routes

[status: implemented]

> – *agent note:* 2026-08-02: bible/link-href+link-html ? /dabar?book=&chapter=&verse=; live (bible/link-html "Gen" 1 1 "") anchors Gen 1:1. bible/render-body handles (bible-ref ?) outline form; garden-import normalizes [[bible:?]].
>
> *[verify] smoke: (bible/link-html "Gen" 1 1) anchors to /dabar?book=Gen&chapter=1&verse=1;*
> *smoke: (bible/parse-ref ?) accepts Gen/Genesis forms used by link helper;*
> *smoke: note body with (bible John 3 16) renders clickable study link;*
> *smoke: bad book degrades to escaped prose, no crash*

notes.links-and-roam owns authoring syntax and reindex rules. This subsection owns the RENDER TARGET helpers.

SYNTAX (canonical in note bodies): (bible BOOK chapter) (bible BOOK chapter verse) (bible BOOK chapter verse-from verse-to) (bible BOOK chapter verse "label") ; optional label string

HELPERS (bible/ package; dabar may wrap chrome): (bible/link-href book ch verse?) -> "/dabar?book=&chapter=&verse=" (bible/link-html book ch verse? label?) -> anchor HTML Reuse bible/abbrev-of + bible/parse-ref + safe-chapter.

RENDER PIPELINE: roam/render-body (or kernel render-links) recognizes the bible sexp form and calls bible/link-html. Optional htmx onto #dabar-panel when the page includes dabar chrome; plain href navigation is always correct.

IMPORT: Obsidian [[bible:Genesis2:3|L]] normalizes to sexps in notes.garden-import – not re-parsed as wiki slugs.

NON-GOAL: storing bible edges in note-link; canon text stays shared data_rows (bible-verse), not duplicated into gardens.

search-fts

Postgres full-text search over verse text (not semantic)

[status: partial]

– *agent note:* 2026-08-02 confirm partial: bible/search = find-text ILIKE on bible-verse text (live "love" ? 40 hits + UI form). True tsvector/rank FTS + index still optional WP.

[verify] smoke: bible/search love returns ranked hits

OPTIONAL WP: expression index / tsvector on data_rows.fields-»'text' for type bible-verse, or generated column in a later migration. Prim: find-text-fts or specialized bible search SQL. NON-GOAL: pgvector, embedder, /api/search/semantic.

daily-scripture

Verse-of-the-day, pushed to yourself: a deterministic picker, a deliver fn that lands the verse in your daily note and pings ntfy, fired by a jobs schedule. The product answer to 'at the very least I want to push daily scripture to myself.'

[status: planned]

– *agent note:* 2026-12 plan pass: daily-scripture campaign. Substrate is ALL shipped – jobs/schedules (borge/jobs.borg), bible/random-row+verse+chapter-counts, calendar's daily-YYYY-MM-DD note convention, notes/doc upserts. New work pinned: this subsection's two Nopales fns, image.outbound-http's http-post, notify.ntfy-delivery's ntfy/send.

*[verify] build: dune build image; smoke: (dabar/daily-ref) called twice on the same day returns the same ref; advances next day; smoke: (dabar/daily-deliver) appends a (bible ?) ref + verse text outline node to notes doc daily-<today>; second call same day is a no-op (idempotent); smoke: (submit-job "dabar/daily-deliver" '()) -> job row done; daily note grew exactly one verse node; smoke: (schedule "daily-scripture" "30 6 * * *" "dabar/daily-deliver" '()) then (schedules) shows it; PP_TZ respected in cron fire time*

THE PICKER (dabar/daily-ref). DETERMINISTIC, not random: n = days-since-epoch (floor (now-ms) / 86400000) verse-index = n mod total-canonical-verses (~31086 BSB rows) walk = book ordinal -> chapter-counts (bible/chapter-counts) -> (book chapter verse) Same verse for every habitat user on the same day, survives re-fire, no state to store, annual-ish cycle. bible/random-row stays the Surprise control; it is NOT the daily picker.

THE DELIVERY (dabar/daily-deliver). Three writes, one job: 1. Verse text via (bible/verse book ch v). 2. Append into the DAILY NOTE (slug daily-YYYY-MM-DD, the calendar package's convention – calendar/has-daily? then shows the dot organically) as an outline node carrying a (bible BOOK ch v) ref body -> note-bible-links renders it as a one-click dabar study link. NOT notes/capture into the Inbox: daily capture is a refile chore; the daily note is where underlining/annotation happens. 3. (ntfy/send title body click-url) – lock-screen ping; Click: opens /dabar?book=&chapter=&verse= (the existing dabar/verse-study-from-params route).

IDEMPOTENCY: deliver checks the daily note's outline for an existing node whose body carries today's dabar/daily-ref before appending (jobs re-fire after retry must not double the verse). with-step exists if the fn grows real stages; the dedupe check is honest enough for v1.

THE SCHEDULE. Pinned at schedule time by the jobs substrate (submitted_by + branch, jobs.node-shapes): the SCHEDULER defines dabar/daily-ref + dabar/daily-deliver on their own branch (garden rule – admin/personal or a dev branch, then promote), then upserts: (schedule \"daily-scripture\" \"30 6 * * *\" \"dabar/daily-deliver\" '()) Cron strings evaluate in image-local time; PP_TZ or offset the cron fields, pinned at make time.

PROMOTE POLICY: the picker + deliver fn are shared-default worthy (system/main) once dogfooded; each user's schedule row and notification target stay personal (jobs rows are submitted_by-scoped).

work-packages

Core dabar features

[status: implemented]

Provides Strong's lexicon lookup and word-level interlinear study tools that build upon the bible/ reader. Includes navigation (prev/next/random) and optional full-text search over verse text.

NOT THIS CHAPTER: personal notes/bookmarks – separate module.

ACCEPTANCE v1 "dabar on PP": - bible reader green on boot - load-library dabar adds study without breaking /bible - Strong's lookup + real interlinear corpus seed (–book John dogfood, then full corpus) - plain/interlinear htmx toggle on reader + study views - no semantic search - no notes/bookmarks here

> – *agent note:* 2026-08-02: v1 acceptance met – bible+dabar libs, Strong's, interlinear toggle, /dabar+/strongs live. Meta checklist subsection, not a separate code deliverable.

non-goals

Explicit exclusions

[status: implemented]

- Semantic search / pgvector / llama embedder - Personal notes / bookmarks (separate module) - Porting Dream dabar server into the image - Audio - Path-param routes /bible/John/3 until platform supports - Multi-translation UI - New unikernel or service binary for dabar

> – *agent note:* 2026-08-02: documentation-only exclusions; marked implemented as spec-complete.

25 borge/notify.borg

pricklypear-notify

Pricklypear book chapter: notify – getting events out of the image to a human. Server-push via ntfy (HTTP POST from a jobs schedule) is the v1; an inhabitat unread feed is the named next surface. Records the trigger-split: server-known events push from the image; locally-known events are the client lens's business (local-first.borg), never this chapter's.

[status: planned]

> – *agent note:* 2026-12 plan pass: chapter born from the daily-scripture discussion. Key recon that shapes it: (a) the Net effect tag and a curl-backed, admin/agent-gated http-get ALREADY ship (image/lib/prims_net.ml, lisp/lib/effect.ml); (b) jobs + cron schedules are live (borge/jobs.borg); (c) the ONLY missing kernel piece for push is image.outbound-http's http-post. The split that must not blur: server-known triggers (cron, chat mentions, shared events) push from the image – the phone need not run anything; locally-known triggers (lens-computed reminders while offline) belong to a resident agent on the client (Termux:API / WorkManager per local-first.borg), not to this chapter.

notify

Delivery of image-side events to humans. jobs.borg says 'result delivery is pull, not push'; this chapter is the sanctioned push exception – narrow, outbound-HTTP-based, identity-gated.

[status: planned]

ntfy-delivery

libs/ntfy – one POST per event to an ntfy topic; the ntfy Android app (or any UnifiedPush distributor reading the same topic) turns it into a native lock-screen notification. No native app development on our side.

[status: planned]

> *[verify] smoke: (load-library "ntfy") then (ntfy/send "t" "b") POSTs to the configured topic (observe via the ntfy app or topic URL); smoke: ntfy/send raises transient on unreachable host (job runner retries per jobs.runner backoff); smoke: ntfy/send returns the payload dict for 4xx/5xx (caller can inspect); topic config row missing -> clean User_error, not a crash*

PACKAGE: libs/ntfy (own lib, standalone – NOT inside dabar; daily-scripture is its first consumer, not its owner).

SURFACE: (ntfy/send title body) ; no click target (ntfy/send title body click-url) Built on (http-post url headers-json body) (image.outbound-http). Wire headers the ntfy convention: Title: <title> Priority: default Tags: <+optional> Click: <click-url> (Icon/Actions/Markdown stay available as pass-through header extras if a caller wants them – headers-json is the escape hatch; the convenience surface stays three args.)

CONFIG (capability secrets OFF branches): A data row of type ntfy-config, id \"default\", fields {url, topic, token?}. url+topic are capability URLs – treat like passwords: the row is admin-readable (data.u.<admin>), never seeded to system/main, never in git. token is ntfy's optional bearer for protected topics. ntfy/send reads the row per call (cheap, and lets the user rotate a topic without touching code).

SELF-HOST PATH: ntfy is a single static binary; pointing ntfy-config.url at a self-hosted instance is a config change, not a code change. The third-party dependency is a choice, not an architecture.

RETRY DISCIPLINE: ntfy/send does NOT catch transient Prim_errors – callers inside jobs let the runner's attempts/backoff own retries (jobs.runner). Callers in request paths (e.g. chat mention fan-out later) wrap in guard themselves or fire via submit-job.

in-habitat-feed

DEFERRED next surface: a (notify title body link) fn + per-user notification rows + an unread-count badge in the layout chrome that hx-polls. The pull-side 'inbox flow' generalization – every package (todo due-soon, flashcards due, chat mentions) gets a uniform in-image feed before any push adapter runs.

[status: planned]

DESIGN (named, deliberately unbuilt): one package-owned type notification {title, body, link, read bool, created_at} in data.u.<user>, written by a plain package fn (no new prim – create + a badge fragment; ship it as libs/notify when built). The layout chrome gains one hx-poll fragment for unread count. Delivery adapters (ntfy, in-habitat, future web-push) fan out FROM this write when it exists: today dabar/daily- deliver calls ntfy/send directly and that is FINE – the feed is additive when it lands, not a prerequisite.

REASON FOR DEFERRAL: daily scripture doesn't need it; the badge is chrome work across themes; and the notification register's exact shape (per-type read cursors? retention? issue-register reuse?) deserves its own dogfood round rather than being rushed as daily-scripture scaffolding.

non-goals

Delivery paths considered and rejected/deferred, with reasons (recorded 2026-12 discussion)

[status: implemented]

- XMPP – rejected. A send-only client is still a protocol stack (SASL/TLS/roster/carbons edge cases) and phone push through XMPP depends on the server's FCM/APNs modules anyway. Its real value (federated chat) is serviced by chat/ in-habitat. Wrong shape for a single-image Lisp OS. - Web Push (RFC 8291) – deferred, not rejected. Makes the browser the push target (PWA, no third party) at the cost of VAPID + aes128gcm/ECDH payload encryption in OCaml plus a service worker. The trigger to revisit: the ntfy third-party dependency becomes intolerable. - Direct FCM/APNs + native app – deferred to the client story. Belongs to local-first.borg's Termux/Termux:API/ WorkManager clients, where termux-notification and the ntfy app's UnifiedPush-distributor role already cover it; an own APK is an optional UX promotion there, not a notification necessity. - Outbound SMTP – unnecessary: email-via-HTTP-API (Resend/Postmark-shaped) is a header set on the same http-post prim if ever wanted; no SMTP client lands. - Server-sent events / WebSocket browser push as a notification channel – the htmx poll cadence already covers in-tab freshness cheaply; SSE exists for the agent surface and is not a notification bus.

26 borge/migrations.borg

pricklypear-migrations

Pricklypear book chapter: migrations
[status: partial]

– *agent note:* 2026-08-02 status reconcile: applied-by-image+additive-only match ops; branching-interaction stays partial (type_defs merge/schema_vers messaging).

migrations

Schema evolution: image-applied, additive-only, schema authority in main
[status: partial]

[verify] build: dune build image; smoke: image boots against a fresh database; schema_migrations records 001..007; re-boot is a no-op

applied-by-image

The image owns schema state before it serves
[status: implemented]

The IMAGE runs migrations. On boot it applies any pending migrations in version order, and only then starts serving. (scripts/dev.sh applies them directly in the dev habitat.) Images assume "the schema is current" once boot completes.

Migration source: SQL files in migrations/ (version-numbered). Tracked in the schema_migrations table; application is idempotent (IF NOT EXISTS guards), so re-applying is a no-op.

Initial migrations: 001_branches.sql – code store tables (branches, function_defs, type_defs, view_bindings, sessions, schema_migrations) 002_auth.sql – auth tables (users, credentials, auth_sessions, auth_log; system_keys is inert legacy) 003_data.sql – shared data_rows 004_bible_ref_index.sql – bible lookup indexes 005_ai_sessions.sql – agent conversation store (ai_sessions, ai_messages; NOT auth_sessions). Spec: ai-authoring.agent-portal. 006_route_visibility.sql – view_bindings.visibility text NOT NULL DEFAULT 'private' (public|private). Spec: auth.route-visibility. Additive column only; existing routes stay private. 007_media.sql – media_blobs (bytea object store for agent/browser image upload). Spec: storage.media. Shared across branches like data_rows; ownership via author column. Additive table only. 008_agent_users.sql – agent user rows / allow flags. 009_tree.sql – one-tree substrate (tree_nodes, tree_branches, bidirectional deferred mirrors, tree_* read views, tree_verify). Spec: one-tree. 012_code_history.sql – code_history table + BEFORE UPDATE/DELETE triggers on function_defs, type_defs, view_bindings. Append-only before-image history for every code-row write. Spec: branching.code-history. 015_jobs.sql – durable background jobs (jobs, job_steps, schedules) as a DEDICATED table (not data_rows/tree nodes): the runner's SKIP LOCKED claim protocol needs real typed status/run_at columns + partial jobs_claim_idx; kernel rows belong to the migration tier. Spec: jobs. 018_tree_versions.sql – ADDITIVE versioned-leaf table for tree-time (branch_id, path, gen) append-only history + covering index + tree_generations row, gen-range partitioned for retention GC, tombstone representation. DESIGNED in tree-time.migration-018 (campaign 5.0 plan pass); the file lands with 5.1 (make versioned-leaves) and is not yet tracked. Spec: tree-time. 019_tree_version_shadow.sql – tree-time Phase 1 dual-write shadow: AFTER trigger on tree_nodes appends a tree_versions row per write (allocating the head gen per path class) + tombstone on delete. Additive; Spec: tree-time.versioned-leaves. 020_tree_version_echo_guard.sql – tree-time mirror- echo guard: tree_version_append() REFINED to make

a no-op mirror bounce (same content body/author/kind/ type) return before allocating a gen or inserting a version row, so one logical write is never double-counted. Additive CREATE OR REPLACE; Spec: tree-time.versioned-leaves. 021_tree_versions_reconcile.sql – tree-time head reconciliation tool: tree_versions_reconcile_heads() heals the one non-head-equivalent class (a shadowed LIVE row whose newest version is a TOMBSTONE – delete-then-recreate whose re-create did not re-shadow) by appending the live content as a fresh head, and repairs the branch/data head counters to the max live gen. Additive CREATE OR REPLACE; runner: scripts/reconcile_tree_version_head.sh. Spec: tree-time.versioned-leaves. 022_tree_retention.sql – tree-time.gc retention worker: tree_retention_policy (policy AS HABITAT DATA, path_class code|data, type_name NULL = whole class, UNIQUE(path_class,type_name)) + tree_ versions_retain(path_class, keep_windows): computes the whole-class floor from the live head gen, CHECKPOINTs the newest in-retained-past state of every fully-retired path to a row at the floor boundary, then DROP PARTITIONs every lazy gen-window entirely below the floor – never the base gen_0 window. Additive + idempotent + image-applied; the worker runs on the jobs runner (boot.ml, migration-015) gated by wall-clock. Spec: tree-time.gc.

A migration in flight blocks serving until it completes (or fails). This guarantees the image always sees a consistent schema. Migration failure aborts boot and requires manual intervention – no half-applied state. (The additive-only policy makes failure recovery simpler.)

> – *agent note:* 2026-08-02: migrations/001-012 + schema_migrations; apply via scripts/dev.sh and deploy hooks before serve (AGENTS.md). Idempotent SQL files.

additive-only

Schema changes can ADD, not remove or rename

[status: implemented]

> *[verify] build: grep -rE 'DROP|RENAME|ALTER COLUMN TYPE' migrations/ = 0 matches; smoke: all migrations idempotently re-appliable*

Schema evolution policy for type_defs in main: ADDITIVE ONLY. You can: - Add a new type (new table) - Add a new field to an existing type (ALTER TABLE ADD COLUMN, with NOT NULL forbidden unless a DEFAULT is specified)

You CANNOT: - Remove a field (no DROP COLUMN) - Rename a field (no RENAME) - Change a field's type (no ALTER COLUMN TYPE except widening)

WHY: - Additive changes are backward-compatible with running images. An image running old code that doesn't know about a new field still works; it just ignores the column. - Removing/renaming breaks running images that reference the field, with no compile-time error to catch it (Nopales is dynamic). - The cost is cruft accumulation: dead fields pile up over time. Tradeoff accepted for correctness.

When a field truly must go: a manual migration (off-cycle, admin-run during scheduled downtime) that also updates affected branch code. This is rare and treated as an incident, not routine.

This policy is set early because retrofitting it later (after non-additive migrations exist) is expensive. It is a foundation constraint.

branching-interaction

How migrations interact with branches

[status: partial]

Migrations only apply to the SHARED data tables, governed by main's type_defs (which are merge-governed into main).

Branches CANNOT migrate data tables. A branch can PROPOSE a type change in its type_defs, but the underlying table doesn't change until that proposal is merged to main and the image applies the resulting migration at next boot.

A branch running code that references a field added in main but not yet handled by the branch's own code: works (the column exists; branch code ignores it on write, reads null on read if no default).

A branch running code that references a field that DOESN'T exist (because the branch's type_defs is behind main's): runtime error at the primitive layer. The user gets a clear message: "field X not in current main schema; merge your schema change or sync to main".

Schema version is tracked per type (schema_vers in type_defs). Branches see the version they declared; main sees its current version. The primitive layer can validate against either at query time.

> – *agent note:* 2026-08-02 confirm: shared tables + additive-only policy live; type_defs proposal?main migration path and schema_vers messaging still incomplete.

27 borge/formal-verification.borg

pricklypear-formal-verification

Book chapter: formal verification of the OCaml outer shell.
[status: planned]

– *agent note:* 2026-08-02 status reconcile: correctly still planned – design in docs/formal-verification-plan.md; no QCheck/proof islands shipped as product gate yet.

formal-verification

Machine-checked stability for the pure OCaml core; the Nopales garden may stay janky. Formal verification proceeds via property-based testing (QCheck) and proof tools. The detailed plan (islands, tooling, passes, success criteria) lives in docs/formal-verification-plan.md.
[status: planned]

28 borge/ai-authoring.borg

pricklypear-ai-authoring

Pricklypear book chapter: ai-authoring
[status: implemented]

> – *agent note:* 2026-08-02 status reconcile: tools/portal/ast-rewrite/growth-seed already impl; review-merge is existing branch+inspect+merge path (no separate AI privilege); provenance v1 agent:<model> on propose-function. Deferred: badge styling, audit table.

ai-authoring

AI as a first-class author of functions: propose, surgical AST rewrite/freeze, growth-from-seed, human merge gate, provenance
[status: implemented]

> *[verify] build: dune build @all; smoke: AI propose on user branch -> human inspect -> merge policy gate; smoke: future: llm-inner freeze rewrites stored AST; llm-seed grows outward on a branch*

AI is an author, not a privileged runtime. Machine- written code uses the same store, branch, and merge machinery as human code. Default trust model: AI writes only to a user (or agent) branch; promoting into system/* still requires admin merge policy.

Coding styles supported by the tool surface:

1) Blank-slate propose (propose-function 'name "spec") Whole new/replaced binding from a prompt.

2) Surgical freeze rewrite (CODING TOOL – preferred) (llm-inner 'name "concept") (llm-outer 'name "concept") LLM rewrites one AST component; on accept the result is FROZEN into function_defs (not left as an unevaluated hole). Emacs-ish replace-region with generated code, but tree-native.

3) Growth-from-seed (CODING TOOL) (llm-seed "build an app that ...") Recursively: create smallest clean core, then llm-outer until requirements are satisfied. Bottom-up / inside-out Nopales style operationalized.

4) Runtime generative eval (SECONDARY / later) Eval-time expansion of AI holes without freeze. Useful, but not the primary coding workflow.

Non-goals for first cut of new tools: - AI does not bypass author-runs-as-author - AI does not write system/* without merge policy - full addressable node table not required for whole-function inner/outer (paths into JSONB AST suffice); node IDs are a later upgrade (branching.ast-nodes)

tools

How an AI proposes or patches functions into the store
[status: implemented]

> *[verify] build: dune build image; smoke: POST /api/ai/propose ai-double then (ai-double 21) => 42*

v1 SHIPPED: - propose-function Nopales prim + /api/ai/propose - whole-function body from model, define on current branch - author = agent:<model> - never merges to system/* - local or remote OpenAI-compat endpoint via env LLM_API_BASE / LLM_API_KEY / LLM_MODEL

Shared client contract for ALL AI tools: - chat/completions (stream optional; SSE for live UI) - model returns code/AST only for author modes - parse gate before any store write - effect inference after parse (lisp-interpreter.effects) - policy gate before freeze

Primary guest surface is agent-portal: durable sessions + one tool-capable loop ((agent-say sid prompt)). Full message history is resubmitted each provider call. propose-function / llm-* remain specialized authoring helpers outside the conversation store.

Sibling tools (exist as prims; product UX secondary): - ast-rewrite: llm-inner / llm-outer / llm-rewrite - growth-seed: llm-seed recursive outer growth

agent-portal

One durable agent: sessions + messages in Postgres, one tool-capable loop, full history resubmitted each provider call

[status: implemented]

> *[verify] build: dune build image; test: image/test/ai_store_test.ml; smoke: migration 005 creates ai_sessions + ai_messages; smoke: ai_store create/list/append/load round-trips a multi-turn thread; smoke: (agent-say sid prompt) resumes prior messages across process restart; smoke: tool turns persist assistant tool_calls + tool results in order*

==========
PRODUCT (finished shape – small and closed) ==========

An agent conversation is a durable thread owned by a user: - seed (system persona) fixed at create - ordered messages (user / assistant / tool) - optional tools allowlist on the session - every model call resubmits [system seed] + history

There is ONE loop. Tools are not a second product: - model may answer in text, or request allowlisted tools - kernel runs tools, appends results, continues - one-shot Q&A is the same loop with a short history

NOT in this product cut: - separate (agent) vs (agent-task) kernels - in-memory-only multi-turn that dies with the request - token streaming as a requirement (progress events yes) - chat UI polish (REPL/pp_eval + thin HTTP enough) - propose-function / llm-* merge into sessions (those stay specialized authoring helpers)

==========
PROVIDER CONTRACT (do not invent a second one) ==========

OpenAI-compatible POST /chat/completions:

{ model, messages: [...full history...], tools?: [...] }

The provider does not remember prior turns. "Multi-turn" means WE store messages and resubmit them every call. Tool rounds are ordinary messages in that list: assistant + tool_calls, then role=tool results, then another completions call with the longer list.

Default transport: non-stream chat_turn (reliable on Synthetic). Progress via on_event: Token | Tool of {name; summary} | Done | Fail HTTP may SSE those control events. Token stream:true is optional later, not part of acceptance for this cut.

==========
SCHEMA (migration 005_ai_sessions.sql) ==========

Additive-only. Named to avoid clash with fleet 'sessions' and auth 'auth_sessions'.

ai_sessions: id uuid PK default gen_random_uuid() owner text NOT NULL – username (whoami) title text – optional; first user line ok seed text NOT NULL – system prompt; not a message row branch_ref text – branch at create / last say tools boolean NOT NULL DEFAULT true model text – snapshot of LLM_MODEL at create created_at timestamptz NOT NULL DEFAULT now() updated_at timestamptz NOT NULL DEFAULT now()

ai_messages: id uuid PK default gen_random_uuid() session_id uuid NOT NULL REFERENCES ai_sessions(id) ON DELETE CASCADE seq int NOT NULL – dense order from 0 role text NOT NULL – user|assistant|tool – (system is session.seed only) content text – nullable for pure tool-call – assistant turns tool_calls jsonb – [{id,name,arguments}] or null tool_call_id text

– set when role=tool created_at timestamptz NOT NULL DEFAULT now() UNIQUE (session_id, seq)

Indexes: ai_sessions (owner, updated_at DESC) ai_messages (session_id, seq)

Invariants: - seed lives ONLY on ai_sessions (no role=system rows) - messages are append-only in v1 (no edit/delete mid-thread except whole-session delete) - owner isolation: list/get/delete scoped to whoami - tools flag is session-level; per-turn override later

==========

STORAGE INTERFACE (image/lib/ai_store.ml) ==========

Pure store module over Store.t / pgx. No LLM calls here. Maps rows <-> Llm_client.chat_message for the runner.

Storage interface (ai_store.ml): create / get / list / delete sessions (owner-scoped); list and append messages (ordered by seq; roles user|assistant|tool only). Session row: id, owner, title, seed, branch_ref, tools allowlist, model, timestamps. (chat_message list) -> unit (* assigns next seq values; touches updated_at *) touch_session store ~id ?title () -> unit messages_for_api session history -> chat_message list (* Msg System seed :: history *)

chat_message encoding: Msg {User|Assistant; content} -> role, content, tool_calls=null, tool_call_id=null Assistant_tools {content; tool_calls} -> role=assistant, content, tool_calls=jsonb Tool_result {tool_call_id; content} -> role=tool, content, tool_call_id System messages are NEVER stored; only injected at API build.

Errors: missing session, owner mismatch, bad role on write. Use Store.current_conn so with-transaction works if needed.

==========

ONE RUNNER (after storage; same subsection product) ==========

Agent.run_loop ~session ~tools ~on_event ~max_steps : string Lwt.t

Algorithm: 1. history = list_messages(session.id) 2. loop step: msgs = messages_for_api session history turn = chat_turn ~messages:msgs ~tools:(if session.tools then allowlist else []) match turn with | Final text -> append [Msg Assistant text]; on_event Done; return text | Need_tools {content; tool_calls} -> append Assistant_tools; for each call: run allowlisted tool; append Tool_result; on_event Tool {...}; continue (cap max_steps) | Turn_error e -> on_event Fail; return error string

Guest entry (prims; wire after store): (agent-session-new seed) -> sid (agent-say sid prompt) -> text append user msg, run_loop, return final assistant text (agent-history sid) -> list of role/content pairs (agent-sessions) -> recent threads for whoami (agent-session-delete sid) -> ok

Library (libs/ai) becomes thin: ai/ask = new-or-sticky session + say (tools may stay on) ai/do = same (explicit tools session) Deprecated as peer kernels (keep temporary aliases): (agent seed prompt) -> new session + one say (agent-task prompt) -> new tools session + one say

propose-function / install-function remain OUTSIDE this loop as one-shot authoring helpers (they may share llm_client.chat_turn but not ai_sessions).

==========

CAPABILITY / PROGRESS / NON-GOALS ==========

Capability: prims labeled Ai (existing effect lattice). Progress: on_event / optional SSE control events. Not required: OCaml 5 effects, WebSocket mid-turn input, message edit, shared multi-user threads, token streaming.

MAKE ORDER 1. migration 005 + scripts/dev.sh apply list 2. image/lib/ai_store.ml + dune + round-trip test 3. run_loop on ai_store (replace in-memory agent_task msgs) 4. prims + libs/ai aliases 5. HTTP session_id on /api/agent (thin)

ast-rewrite

Surgical coding tools: llm-inner / llm-outer / llm-rewrite with freeze-on-accept into stored AST

[status: implemented]

[verify] build: dune build image; smoke: llm-inner on a binding rewrites body AST and survives reload; smoke: llm-outer wraps a pure function; effect badges update; smoke: reject unparseable model output without mutating store

PURPOSE Iterative code growth/refactor against live stored trees. Human (or command) supplies a concept; model rewrites ONE component; accept freezes into Postgres AST + live env.

PRIMS / COMMANDS

(llm-rewrite name prompt . options) General form. Options may include: mode: 'replace | 'wrap ; default replace path: structural path ; default whole body as: new-name ; non-destructive rename target branch: branch-ref ; work on a branch first accept: 'auto | 'preview ; default preview in UI, ; REPL may auto with flag

(llm-inner name prompt . options) Sugar: mode=replace on function body (or selection path). "Improve/replace the organ."

(llm-outer name prompt . options) Sugar: mode=wrap on whole function. "Put tissue around the organ." Old behavior preserved via call-through or careful inline; prefer call-through to name-old or nested original subtree.

FREEZE-ON-ACCEPT SEMANTICS (critical) 1. Load current function AST from store/env 2. Select target subtree (body / path / whole) 3. Build surgical prompt (see PROMPT CONTRACT) 4. Ping LLM local or remote 5. Parse response as s-expr or JSON AST only 6. Splice into tree (replace or wrap) 7. infer_effects on result 8. policy check (default allow Pure|ReadDb|Html; escalate WriteDb|Branch|Publish|Ai) 9. Preview diff (pretty + optional AST) 10. On accept: - persist function_defs.body JSONB - rebind live env - author = agent:<model> - optional provenance run id 11. On reject: no store mutation

This is NOT leaving (llm-inner ...) in the program. After accept, the program contains real Nopales AST only.

PROMPT CONTRACT (surgical AST author) System: You are editing a Pricklypear Nopales AST. Return ONLY one replacement form: a single s-expression (or JSON AST). No markdown, no essay. You write ONE component of a larger program tree.

User payload includes: - mode replace|wrap - function name - user concept / intent - current function pretty - current function AST json - selected path + selected subtree pretty/json - available prims summary - allowed effect set - for wrap: instruction to preserve behavior and call through original unless inlining is clearer

Model output: - full lambda when replacing whole binding body - subtree only when replacing a selection hole - wrapper lambda when mode=wrap

VALIDATION GATES - reader/json parse success - splice shape compatibility - effect policy - optional smoke eval of (name sample-args) if provided

UI SURFACE - function editor command: Rewrite? / Wrap? - structural selection path when structure mode exists - REPL prims for power users - always show diff before freeze unless accept:'auto

DEFAULTS (safety) - prefer work on current branch; offer agent/* branch - prefer preview over silent overwrite - keep old body in diff buffer / one-level undo - non-destructive 'as new-name always available

NON-GOALS (this subsection) - recursive app growth (see growth-seed) - runtime hole expansion without freeze - multi-file repo patches

growth-seed

llm-seed: recursive bottom-up growth via smallest core + repeated llm-outer until requirements satisfied

[status: implemented]

[verify] build: dune build image; smoke: llm-seed on a tiny goal produces >=1 frozen function on a branch; smoke: growth stops at max-steps or requirement-satisfied judge; smoke: each step is inspectable as a frozen binding + diff

PURPOSE Operationalize inside-out Nopales development for AI: seed a minimal clean function, then wrap/grow until the stated requirements are satisfied.

TOP-LEVEL COMMAND

(llm-seed requirement . options)

Options (sketch): name: optional root name hint branch: default fork to user/ai-<stamp> or agent/* max-steps: default small (e.g. 4..8) budget: token/time caps effects-allow: default Pure|ReadDb|Html stop: 'ask | 'auto-judge

ALGORITHM (orchestrator, not one giant prompt)

Step 0 – Plan (optional short call) Given requirement, emit a growth outline: core behavior, successive wrappers, final page? Human may edit plan later; v1 can be implicit.

Step 1 – Seed (smallest clean core) Prompt specialty: "Write the SMALLEST and CLEANEST pure-ish function that captures the essential nucleus of: <req>. One lambda only. No wrapping, no IO unless required." Freeze as seed name (e.g. notes-core). Run a tiny smoke if possible.

Step 2..N – Grow outward (llm-outer loop) While not satisfied and steps < max-steps: a. Judge prompt (or human): "Does current function set satisfy <req>? If not, what SINGLE outer responsibility should be added next (validation, IO, page, composition)?" b. If satisfied -> stop c. Else llm-outer on current tip with that single responsibility (surgical wrap prompt) d. Freeze wrapper as new tip (or replace tip name while keeping -vN history / old symbol) e. Record step in the run's growth log (in-memory; durable step history is a later addition)

Step Final – Optional publish surface If requirement implies a page and effects allow: define page handler + (route ...) Still no auto-merge to system/*.

JUDGE / STOP CONDITIONS - model judge returns satisfied=true - human stops - max-steps reached - effect escalation would exceed allowlist - parse/policy failures exceed retry budget

WHY RECURSIVE OUTER NOT ONE-SHOT APP DUMP - preserves a working center at every step - each layer is runnable/testable in the image - matches bottom-up Nopales craft - forces LLMs into step-sized commits - diffs remain reviewable

PROMPT SPECIALIZATIONS Seed prompt: smallest nucleus, prefer Pure Outer prompt: one responsibility only, preserve prior behavior via call-through Judge prompt: boolean satisfied + next missing capability in one short structured response

FAILURE MODES / GUARDRAILS - onion wraps forever -> max-steps + dedupe judge - outer reimplements instead of wraps -> prompt + validation heuristic (must reference prior name) - effect creep -> policy gate per step - nondeterminism -> provenance + branch + growth log

RELATIONSHIP TO OTHER TOOLS llm-seed USES: - blank-slate propose or llm-inner for seed - llm-outer for each growth ring - effects inference/policy each freeze - review-merge for promotion to system/* llm-seed is an orchestrator over ast-rewrite.

NON-GOALS - fully autonomous unattended product engineering - hidden multi-minute agent swarms without logs - replacing human taste for when to re-inner/ collapse wrappers after growth

review-merge

Human gate: inspect AI changes, then merge with existing policy

[status: implemented]

Review loop: 1. AI commits one or more function_defs on a branch (propose, llm-inner/outer freezes, or llm-seed steps) 2. Human opens system browser / functions list / editor / inspect to read AST + effect badges 3. Human runs/tests via browser-repl or scripts/repl.sh 4. For growth-seed: step through growth log diffs 5. Human merges branch -> target via existing (merge ...) policy (admin-only into system/*) 6. Reject path: leave branch, redefine, or undo freeze

No separate "AI merge" privilege. Merge politics stay in branching.merge.

> – *agent note:* 2026-08-02: workflow uses /bindings inspect + /branches promote/merge + REPL – no separate AI merge. Matches "merge politics stay in branching.merge".

provenance

Attribution, audit, and trust labels for machine-authored code

[status: implemented]

v1 SHIPPED: author=agent:<model> on AI writes; visible in /bindings and inspect.

REQUIRED for rewrite/seed tools: - author agent:<model> on every freeze - optional metadata: run_id, parent_function, growth_step, prompt_hash, mode inner|outer|seed - growth-seed writes an inspectable step log

DEFERRED: visual agent badge styling, dedicated audit table. Trust rule remains branch + merge policy + effect allowlists.

> – *agent note:* 2026-08-02: v1 as written in details – author agent:<model> on propose-function/AI writes; inspect shows author. Optional metadata/badge/audit table remain deferred non-blockers.

29 borge/film-analysis.borg

pricklypear-film-analysis

Pricklypear book chapter: film analysis – shot/scene structure, chiastic (ring) analysis, cut comparison as branches

[status: planned]

film-analysis

Films as queryable structure: scenes with frame-exact timecodes, motifs and beats, chiastic analysis over scene rings, and alternate cuts as branches. Analysis is data on the image; media files never are.

[status: planned]

> *[verify] build: dune build image; smoke: (load-library "film") installs film/? bindings and routes; smoke: create a film, ingest scenes, run film/report over a branch; smoke: GET /film lists films; /film/<slug> shows ring report; smoke: pp_eval film/? entry points work for agents*

==========
PRODUCT INTENT ==========
A first-class film-analysis workbench on the live image.

The motivating observation: long-form narratives carry structural meaning in temporal placement – chiastic (ring) composition where scene k mirrors scene n-k+1, a "mirror moment" at the temporal center, timed plant/payoff pairs. This structure is *checkable*, not just interpretable – but no NLE or spreadsheet treats a cut as queryable, branchable data. Pricklypear does.

Three workloads, one substrate: 1. ANALYSIS – structure of published films (the Shining European-vs-US cut comparison is the first corpus). Machine-detected scene boundaries as ground truth on one branch; human curation as a fork. 2. LINTING – report unpaired mirrors, orphan plants, per-pair duration deltas, a whole-cut tightness score. The chiastic claim becomes a number. 3. AUTHORING – later, the same machinery pointed at one's own footage: dailies auto-split, motifs tracked, the cut linted before render.

Domain tension (the whole design): - The interesting claims are EXACT (frame-exact pairing, center-scene identity, tightness scores). - The interesting readings are FLUID (this scene mirrors that one; this beat pays off that plant).

Resolution: scenes/motifs/beats as boring typed rows; chiastic truth DERIVED from position, never stored; human declarations kept as separate fields so the linter can report where declaration and derivation disagree – that disagreement is the analysis.

Inspired by: - ring composition scholarship (Mary Douglas et al.) - craft literature (mirror-moment midpoint, timed beats) - quantitative film studies (Cinemetrics-style shot data) - the corkboard: cards, colored by thread, moved by hand

NOT a video editor. NOT a media store (no frames, no clips – media stays on the laptop; the image holds only structure and metadata). NOT a generation pipeline (AI video gen is a separate future chapter gated on an http prim). NOT a platform for redistributing copyrighted media – the PUBLISHABLE artifact is analysis (numbers, reports, essays), never footage.

Killer property: a cut is a branch. The US cut and the European cut of the same film are sibling branches over shared film rows; "the recut tightened the ring" is a diff of two generated reports.

==========
LAYERING ==========
- libs/film/lib.pp – package film/? (seed on system/main) - data_rows types – film, scene, motif, beat - Routes via (route ?) – /film and report paths - scripts/film_ingest – laptop-side extraction ? Nopales source ? pp_eval (see

ingestion) - OCaml – existing CRUD/list/dict prims only; NO new kernel prims required for v1

Analysis functions are PURE Nopales over (rows ?) results: chiasm/pairs walks a sorted scene list two-pointer style; chiasm/center is the same recursion returning the singleton remainder (odd-length ring) or empty (even-length ring has a center SEAM, not a center scene – both shapes reported).

==========

DATA MODEL (v1) ==========

Types (deftype on load). Timecodes are INTEGER FRAME COUNTS; fps lives on the film row; seconds are a rendering concern.

film slug string ; "the-shining" title string year string fps string number ; "23.976" | "24" | "25" notes string

scene ; ONE detected/curated scene in ONE cut film string ; film slug cut string ; cut label, e.g. "eu" | "us" | "auto-t12" ord string int ; position in THIS cut slug string ; "room237" ("" until curated) summary string tc_in string int ; frames dur string int ; frames mirror string ; DECLARED mirror scene slug or "" ; derivation from ord is the truth; ; this field is a claim to check

motif ; a tracked recurrence film string name string ; "mirror" | "red-key" | ? kind string ; prop | line | color | sound | image

beat ; a motif occurrence inside a scene scene string ; scene id motif string ; motif name role string ; plant | payoff | echo tc string int ; frames, absolute

Why frames-as-strings: data_rows fields are strings; integer frames avoid float rounding across fps conversions. "To the second" claims are rendered, not stored.

NO shot-level table in v1 (shots matter for production, not for ring analysis; a shot type is a later subsection if the authoring workload arrives). NO user ACL – data_rows are shared (existing habitat rule). NO media blobs, thumbnails, or waveforms. Ever. Paths/hashes in notes fields at most.

==========

CHIASM AS DERIVATION (the core idea) ==========

The pairing is positional: in a ring of n scenes, scene k mirrors scene n-k+1. Therefore:

(chiasm/pairs scenes) ; two-pointer recursion: pair ends, ; recurse inward ? list of pairs (chiasm/center scenes) ; same recursion; odd ring leaves ; the CENTER SCENE as a singleton; ; even ring returns '() (center is ; the seam between the middle pair)

The mirror scene falls out of the structure. Nobody annotates it; the report NAMES it.

Report shape (film/report scenes) – a dict/assoc tree: center center scene or center seam shape odd | even pairs per-pair: slugs, dur delta (frames), shared motifs declared declared-mirror mismatches (claim vs position) orphans plant beats with no downstream payoff beat tightness sum of per-pair dur deltas (lower = tighter ring)

The linter's most interesting output is DISAGREEMENT: - declared mirror ? derived mirror ? either the annotation is wrong or the film breaks its own ring deliberately (broken symmetry is itself a finding) - derived pair with strong shared motifs but no declared mirror ? an unnoticed mirror, proposed by the machine

==========

INGESTION (laptop-side, no new kernel prims) ==========

Scene boundaries come from the media file ON THE LAPTOP, never from the image:

ffmpeg -i cut.mp4 -an -vf "scdet=threshold=N,showinfo" \ -f null - ? cut log with pts_time per detected cut

scripts/film_ingest (ksh) parses the log and EMITS Nopales source – (film/scene-create ?) forms – piped to pp_eval over the existing /api/eval endpoint. The image receives already-structured data through the normal eval path.

Known detector limits (documented, accepted): - scdet finds CUTS, not

narrative scenes: dissolves, long fades, and match cuts slip or merge; threshold is per-film tuning. Adjacent detections are merged by hand during curation – this is expected work, not failure. - Detection lands on a MACHINE branch (e.g. cut label "auto-t12"); curation happens on a fork so ground truth stays pure and detector re-runs are diffable.

Optional later sources through the SAME emitter path: - whisper.cpp transcripts ? dialogue beats with timestamps - PySceneDetect XML/EDL export instead of raw ffmpeg logs - frame-similarity pass (pHash / ffmpeg signature) ? PROPOSED mirror pairs (machine seeds, human accepts)

========== CUTS AS BRANCHES ==========

Branch convention (per habitat-workflow session ritual): analysis/<film>/<cut>-auto machine ground truth analysis/<film>/<cut>-curated fork; slugs, mirrors, beats

Cut comparison = run film/report per branch, diff the trees. "The recut tightened the ring" becomes: tightness(eu) < tightness(us), with the per-pair table behind it.

========== PUBLISHING BOUNDARY ==========

Personal analysis of owned media for criticism is the intended use. What MAY be published from the habitat: reports, numbers, essays, generated diagrams. What MUST NOT be: footage, frames, audio, or anything that reconstructs the work. No public routes serve derived media; report routes are private by default.

model

film/scene/motif/beat types; integer-frame timecodes; declared-vs-derived mirror split

[status: planned]

> *[verify] smoke: load-library defines film, scene, motif, beat types; smoke: scene-create stores cut/ord/tc_in/dur as frame integers; smoke: mirror field is a declaration; derivation comes from ord; smoke: fps lives on film; seconds are render-only*

ingestion

laptop-side scdet/ffmpeg ? Nopales emitter ? pp_eval; machine branch stays pure, curation is a fork

[status: planned]

> *[verify] smoke: scripts/film_ingest parses an scdet log into scene-create forms; smoke: ingesting a short clip creates ordered scenes on an -auto branch; smoke: re-ingest at a new threshold lands on a new cut label, old branch untouched*

chiastic-analysis

chiasm/pairs + chiasm/center two-pointer derivation; film/report with pairs, declared mismatches, orphan plants, tightness

[status: planned]

> *[verify] smoke: chiasm/pairs on a known list returns end-paired list; smoke: chiasm/center returns singleton on odd ring, empty on even; smoke: film/report names the center scene from structure alone; smoke: declared mirror mismatch appears in report.declared; smoke: orphan plant (no downstream payoff) appears in report.orphans; smoke: tightness is the sum of per-pair dur deltas*

cut-comparison

cuts as branches; report-per-branch diff answers 'did the recut tighten the ring'
[status: planned]

[verify] smoke: two cut labels over one film produce independent reports; smoke: tightness diff between cuts is computable via pp_eval

ui

routes /film, /film/<slug>; ring report page with per-pair table and rainbow-style arc diagram via render-html
[status: planned]

[verify] smoke: GET /film 200 after load-library; smoke: GET /film/<slug> renders center, pairs table, tightness; smoke: diagram renders arcs between derived mirror pairs

agent-access

pp_eval film/? as the API; reports are data trees an agent can diff
[status: planned]

[verify] smoke: pp_eval film/report returns the full report tree; smoke: pp_eval scene/beats queries work per film and cut

30 borge/film-edit.borg

pricklypear-film-edit

Pricklypear book chapter: film editing – studio library (characters/assets), Nopales-authored EDLs, Blender VSE as headless assembly backend, render caching, gen-API bridge as future edge

[status: planned]

film-edit

Programmatic video editing: the image holds the studio library (characters, locations, props, style locks) and the project graph (shots, cast bindings, takes, EDLs). Blender does assembly and render headlessly; media lives on disk under content hashes. Nopales state is authoritative; .blend files and renders are derived artifacts.

[status: planned]

> *[verify] build: dune build image; smoke: (load-library "edit") installs edit/? bindings and routes; smoke: define assets/characters, a project, shots with cast, choose takes, emit an EDL; smoke: GET /edit lists projects; /edit/<slug> shows cast, shot table, and render state; smoke: pp_eval edit/? entry points work for agents*

==========

PRODUCT INTENT ==========

A REPL-driven video editing and assembly pipeline with pricklypear as the brain and Blender as the muscle.

The motivating observation: an edit is DATA – an ordered list of decisions over takes with in/out points – and every serious editing tool already treats it that way internally (the EDL is the oldest data structure in film). What no tool gives you: the decision list as queryable, branchable, agent-editable rows on a live image, with the GUI reduced to a view.

The pipeline (each stage is data in, artifact out): bible (characters/locations/style) ? lock canonical refs ? script ? shots + cast/ref bindings ? expand prompt+refs from library ? raw footage (gen API or camera) ? N takes per shot ? pick a take ? lines ? dialogue takes (TTS or mic) ? cues (beds + spot SFX) ? assemble (EDL) + sound bounce ? render ? review ? re-cut / regenerate single shots ? optional promote take ? library asset

Every decision is a row: asset locks, cast bindings, prompt, seed, model, backend, cost, rejected takes, chosen take, input snapshots on takes. The whole history is inspectable, forkable, promotable – fork a branch per cut (cast bible forks with it).

Division of labor (settled design, do not relitigate): - PRICKLYPEAR – brain: studio library, project graph, provenance, cost ledger, branching, orchestration vocabulary, prompt/ref expansion, EDL generation, render-cache keys. - BLENDER – muscle: assembly (VSE), compositing, authored animation (deferred, see below), final render. Headless (blender -b) for jobs; a live GUI session is a VIEW onto the same scene state, never the authority. - GEN APIS – rented GPUs over HTTP: video/image gen, premium TTS. Local ComfyUI is a LATER backend behind the same interface, gated on hardware. - FFMPEG/DAW – sound muscle: bounce and mix are derived artifacts of the line/cue graph. An Ardour/Reaper session is a VIEW with the same re-import rule as the Blender GUI; the session file is never adopted as truth. - DISK – media files content-addressed; the image holds hashes + paths + provenance, NEVER blobs for motion or audio masters (UI thumbs may dual-point – see library).

Authority rule (the invariant that keeps this coherent): NOPALES STATE IS AUTHORITATIVE. .blend files and renders are build artifacts, regenerable

from rows. Hand-tweaked .blend truth is forbidden – it silently forks the project away from its provenance. If the GUI is used, its changes are re-imported as row edits (a documented import path), never adopted by copying the file back.

Inspired by: - the edit decision list (Hollywood's oldest data structure – timecode-addressed cuts as text) - build systems: render cache keyed on hash of inputs; change nothing, cache hit - Blender's own architecture: a live persistent image driven from a console – same shape as pricklypear

NOT a human NLE replacement (Kdenlive stays the hand-tool; it can open MLT/EDL exports for human touch-up). NOT a blob store for clips. NOT real-time collaboration. NOT locked to one gen vendor – backends are config, not design.

Killer properties: - Render caching falls out of the object model. The EDL is rows; hashing the canonical print yields a cache key; a render is a memoized pure function of project state. Re-cut one shot, re-render only what changed. - Continuity is a library problem, not a prompt-paste problem. A character is a stable id with a locked appearance bundle; shots bind to ids; gen expands bindings. Fix Mara once, re-gen only shots that cast her.

========== LAYERING ==========

- libs/edit/lib.pp – package edit/? (seed on system/main) - data_rows types – asset, project, shot, shot-cast, shot-ref, take, edl-entry, render-job, line, cue, mix-job - Routes via (route ?) – /edit and project/report paths - services/blender_bridge – OCaml daemon: typed commands in, bpy socket calls out; owns the render job queue - blender/bridge_addon.py – thin socket-eval addon inside Blender; PYTHON IS FIRMWARE, written once, checked in - scripts/render_worker – headless blender -b invocation - New kernel prims – http (client), spawn (subprocess), file-stat/read-bytes-range. Additive, general-purpose; specified in their own subsection below because they are kernel surface, not package code.

v1 vs later, honestly split: v1 (no new prims): studio library + cast/ref bindings, project graph, EDL rows, EDL export to MLT XML + Blender scene script ON DISK, manual render, import of render results, promote still/clip metadata into assets, line/cue sound rows, cue-sheet + ffmpeg script export ON DISK with manual bounce, import of bounce results. Fully useful for bibles, human-driven assembly, and agent-authored structure before any gen API. v2 (prims land): bridge orchestration, job queue, gen-API submission that EXPANDS library bindings and snapshots inputs on each take, render cache automation, TTS batches, automated dailies bounce via spawn – the async loop.

========== DATA MODEL (v1) ==========

Types (deftype on load). Timecodes integer frames, fps on project – same convention as film-analysis.

—- Studio library (stable identity) —-

asset ; character, location, prop, style lock, voice, ? project string ; project slug, or "" studio-wide ; on this branch slug string ; "mara", "diner-ext", "theme-A" kind string ; character | location | prop | ; style | voice | sfx | score | ; plate | still | other summary string bible string ; long notes / backstory / art dir appearance string ; locked positive prompt fragment negative string ; locked negative fragment primary_hash string ; canonical still/sheet/sample primary_path string ; relative to media root ref_hashes string ; JSON list of extra content hashes ; (turnarounds, costume variants) voice_ref string ; voice id or asset slug (kind=voice) lora_ref string ; backend adapter id, or "" media_id string ; optional habitat media_blobs UUID ; for UI thumb ONLY (see boundary) meta string ; JSON bag (non-query essentials)

A character is an asset with kind=character (not a second identity table). Wardrobe/costume variants are assets (kind=prop or kind=still) bound via shot-cast.wardrobe.

—- Project graph —-

project slug string ; "short-01" title string fps string number resolution string ; "1920x1080" budget_cents string int ; spend cap for API gen notes string

shot ; one narrative shot in the current cut project string ord string int ; position in cut slug string summary string ; script beat prompt string ; ACTION/dialogue prompt only; ; appearance comes from cast/refs dur_target string int ; frames, planned

shot-cast ; who appears in the shot shot string ; shot id asset string ; asset id (usually kind=character) wardrobe string ; optional asset id, or "" role string ; hero | featured | background

shot-ref ; non-cast reference bindings (typed, not JSON bag) shot string asset string ; location plate, style, prop hero? purpose string ; ip-adapter | style | depth | ; loc | prop | plate | other weight string ; backend hint, "" ok

NOTE: an earlier sketch had shot.refs as a JSON hash list. That is REJECTED. Cast and refs are rows so "which shots use Mara?" is a closed query. Ad-hoc one-off hashes (no library entry yet) are allowed by first creating a minimal asset (kind=still) or via take-local override fields only at gen time – not a free-form JSON column on shot.

take ; one candidate clip (or still) for a shot shot string ; shot id n string int ; take number backend string ; "fal-wan" | "replicate-ltx" | ; "local-comfy" | "camera" | ? model string ; model/version string seed string cost_cents string int ; 0 for local/camera media_hash string ; content hash of the file on disk media_path string ; path RELATIVE to a media root state string ; pending | done | failed | rejected rating string ; "" | human note on review input_snapshot string ; canonical JSON of EXPANDED gen ; inputs at submit (prompt, asset ; ids, appearance fragments, ref ; hashes, model). Immutable after ; land. Reproducibility + cache. source_assets string ; JSON list of asset ids used

edl-entry ; the cut itself – one row per timeline segment project string cut string ; cut label (branch-correlated) ord string int take string ; take id tc_in string int ; source in-point, frames dur string int transition string ; "cut" | "dissolve:N" | "fade:N" audio string ; take id of TTS/dialogue, or ""

render-job project string cut string edl_hash string ; cache key: hash of canonical EDL state string ; queued | running | done | failed out_hash string ; result media hash out_path string log string

—- Sound (production audio graph) —-

line ; one spoken line of dialogue project string shot string ; shot id the line belongs to ord string int character string ; asset id (voice via voice_ref) text string notes string ; performance: "whisper, rushed" take string ; chosen audio take id, or ""

Audio takes are ordinary take rows on the same shot with backend "tts-*" (premium or local) or "mic" (recorded). line.take points at the chosen one. ADR here means only: a replacement read is a new take + choose; the history of reads is the take list. No special ADR table.

cue ; continuous or spot sound on the TIMELINE project string cut string ; cut label (same as edl-entry) ord string int mode string ; bed | hit asset string ; kind=ambience | score | sfx tc_start string int ; timeline frames dur string int ; hit: 0 means asset length gain_db string number loop string ; "1" to tile a short bed

mix-job ; bounce as memoized function of the audio graph project string cut string cue_hash string ; hash of canonical print of cues ; + chosen line takes + profile profile string ; named preset, e.g. "dailies" state string ; queued | running | done | failed out_hash string out_path string log string

Sound obeys the same build-system rule as picture: the bounce key is a hash of canonical rows; nothing changed means cache hit. edl-entry.audio remains a per-strip dialogue pointer for assembly; lines + cues are the production graph that feeds it.

==========

LIBRARY RULES (characters and assets) ==========

Three layers – do not collapse them:

1. LIBRARY – asset rows: stable identity + locked appearance/voice/ref bundle + bible text. 2. BINDING – shot-cast / shot-ref: usage in a shot. 3. INSTANCE – take rows: what was actually generated or filmed, with input_snapshot frozen at submit.

Expansion (used by gen-submit and by a pure preview prim): (edit/expand shot-id) ? action prompt + each cast asset.appearance (+ wardrobe.appearance) + each shot-ref asset.appearance as appropriate + union of primary_hash/ref_hashes for ref images + voice_ref for TTS lanes That structure is what input_snapshot stores.

Promote path (library grows from production): (edit/promote-take take-id kind slug) ? asset row whose primary_hash/path copy the take's media; optional media_id if a UI thumb is registered. Human may then edit appearance/bible and re-bind shots.

Analysis vs production (boundary with film-analysis): asset/character = production bible (what we generate with) motif/beat = narrative lint (what the cut means) Do NOT merge tables. Optional shared slug later is fine; v1 keeps them independent.

Media boundary (two systems, both legitimate): - MOTION / masters / gen outputs: disk + content hash + relative path only. NEVER Postgres bytea. NEVER a VStr. - UI thumbs / character sheets for browser browse: MAY also use existing habitat media_blobs (storage.media, small image cap) via asset.media_id. Dual pointer is OK; disk hash remains authoritative for gen workers. - Third-party analysis corpus still never publicly routed – film-analysis.publishing unchanged.

NO per-user ACL (existing habitat rule). NO keyframe/curve tables in v1 – authored animation waits for hardware (Cycles on CPU and Eevee without GPU are not viable); transitions are the only motion v1 authors. NO claim that the data model alone fixes identity drift in gen models – the habitat enforces provenance, forced ref bundles, reject/regen economics, and branch+budget. Drift is a model problem; reproducibility is ours.

==========

SOUND RULES (written for people who are not sound engineers) ==========

Audio does NOT cut with picture. Sound is layers in time: lines – dialogue, shot-scoped, one chosen take per line beds – long spans: room tone, ambience, score region hits – spot SFX pinned to a timeline frame That is the whole model. Everything below is habit.

The four jobs, in the order they pay off: 1. dialogue coverage – every line has a chosen take, even scratch (mic whisper or fast local TTS). A cut with complete scratch reads is judgeable as cinema; a silent one is not. 2. presence – one ambience bed per location; cutting to a new room changes the bed. That alone sells space. 3. spot SFX – doors, cloth, footsteps at cut points. 4. mix – dialogue forward, beds well under talk, light limiter. Named presets, not knob archaeology.

Dailies sound profile (the loop v2 automates): chosen picture strips + chosen line takes + cues ? ffmpeg bounce with the dailies preset ? proxy mp4 with sound. Sound must NOT wait on the Blender render bridge; a dailies reel with scratch audio is a daily, a mute 4K master is not.

Voice: character.voice_ref ? kind=voice asset (sample hash + backend voice id). TTS reads are takes (job-shaped in v2, synchronous local in v1); mic reads are takes with backend "mic". Both are equally legitimate. Scratch first, hero reads later – the line id never changes.

Music: score is cues with mode=bed over named regions. Temp tracks are cue rows like any other; the asset row's provenance fields say what may ship. Gen music is takes with the same provenance discipline as picture.

NOT a DAW. NOT a sample store (wav bytes live on disk under hashes like motion masters). NOT auto-lip-sync: a line take is matched to picture by editing (trim, cutaway, hold), not by warping faces to audio.

==========
THE ASYNC LOOP (job-shaped, not call-shaped) ==========
SUBSTRATE: the jobs chapter (borge/jobs.borg) specifies the durable job/step/schedule machinery this vocabulary runs on – gen-submit is (submit-job ?), gen-status is (job-status ?) over the job row; render/mix JOBS claim through the same runner. The memoization-by-hash cache below is film-edit's own and orthogonal to job durability.

Gen and render take minutes. The vocabulary is job-first:

(edit/asset-upsert ?) ; library write (edit/shot-cast shot asset role) (edit/shot-ref shot asset purpose) (edit/expand shot-id) ; pure preview of bundle (edit/gen-submit shot-id :takes 3) ; expands + snapshots ; ? job ids, returns now (edit/gen-status job-id) ; pending | done | failed (edit/takes shot-id) ; landed takes + costs (edit/choose shot-id take-n) ; sets the cut's take (edit/promote-take take-id kind slug) (edit/line-choose line-id take-id) ; chosen read for a line (edit/cue-add cut mode asset tc dur db) (edit/dailies cut) ; proxy mp4 WITH sound (edit/mix cut profile) ; cue_hash ? cache lookup ; ? mix-job (or hit) (edit/render cut) ; EDL hash ? cache lookup ; ? render-job (or hit)

A render is a memoized pure function: same EDL rows ? same edl_hash ? cache hit. Budget is a branch property: fork for a re-gen experiment, spend lives on the branch, main keeps the released cut. Cost queries are closed questions over take rows (spend per project/cut/backend).

==========
BLENDER BRIDGE (protocol sketch) ==========
services/blender_bridge (OCaml, stdlib Unix sockets): - accepts lines from the image over TCP (localhost only): (scene-clear) (strip-add <edl-entry-as-sexp>) (render <out-path>) (status) - translates to bpy calls over the addon's socket - owns a FIFO job queue; one render at a time blender/bridge_addon.py (~100 lines, checked in once): socket server inside Blender eval'ing a FIXED, TYPED command set – not arbitrary code. bpy only. Two modes, same protocol: live – GUI open, bridge attached; the timeline is a live VIEW of row edits (re-import rule applies) batch – blender -b per render job, fully headless

==========
PUBLISHING / MEDIA BOUNDARY ==========
Own footage: fine to serve results via routes if desired. Third-party analysis corpus: media never enters the image, never gets a public route – per film-analysis.publishing.

model

asset/project/shot/shot-cast/shot-ref/take/edl-entry/render-job types; content-hash media refs; cost ledger and input_snapshot on takes

[status: planned]

> *[verify] smoke: load-library defines library + graph types with documented fields; smoke: take rows carry backend/model/seed/cost/media_hash/input_snapshot; smoke: edl-entry rows order a cut with tc_in/dur/transition; smoke: motion masters are hashes and relative paths only – no clip bytes in Postgres*

library

Studio library: asset rows (character/location/prop/style/voice/?), shot-cast and shot-ref bindings, expand + promote-take; dual media pointer for UI thumbs only

[status: planned]

> *[verify] smoke: edit/asset-upsert creates kind=character with appearance and ref_hashes; smoke: shot-cast and shot-ref bind assets to a shot; which-shots-use-asset is a rows query; smoke: edit/expand returns action prompt + cast appearances + unioned ref hashes; smoke: edit/promote-take mints an asset from a landed take's media_hash; smoke: asset.media_id*

optional; gen path still uses primary_hash on disk; smoke: no shot.refs JSON column – cast/ref are typed rows; details

sound

Production audio as data: line rows (dialogue with chosen takes), cue rows (beds + spot hits on the timeline), mix-job bounce keyed on cue_hash; dailies proxy with sound – no Blender dependency

[status: planned]

[verify] smoke: line rows bind text to character and shot; line.take chooses an audio take; smoke: audio takes are ordinary take rows (backend tts- or mic) on the shot; smoke: cue rows place beds and hits on the timeline in frames with gain_db; smoke: export writes a cue sheet + ffmpeg bounce script on disk for a cut (v1); smoke: edit/dailies bounces chosen picture + lines + cues to a proxy mp4 with audio (v2); smoke: mix-job on unchanged audio graph returns cache hit; changing a line take or cue changes cue_hash; details*

edl-and-export

canonical EDL print + edl_hash; export to MLT XML and Blender scene script on disk; re-import path for GUI edits

[status: planned]

[verify] smoke: identical EDL rows produce identical edl_hash; smoke: export writes a valid MLT XML file for a sample cut; smoke: export writes a Blender VSE build script for the same cut; smoke: Kdenlive opens the exported MLT XML without errors

render-cache

render as memoized pure function of EDL; render-job rows; cache hit on unchanged hash

[status: planned]

[verify] smoke: edit/render on unchanged cut returns cache hit, no job; smoke: changing one edl-entry changes edl_hash and queues a job; smoke: render-job records out_hash/out_path on done

blender-bridge

OCaml bridge daemon + bpy socket addon; typed command set; live GUI as view, batch for renders; job queue

[status: planned]

[verify] smoke: bridge addon loads in headless blender and answers status; smoke: strip-add commands from the daemon build a VSE timeline; smoke: render command produces a playable output file; smoke: one-at-a-time queue: second render waits for first

prims-http-spawn

KERNEL SURFACE: http client prim, spawn subprocess prim, file stat/read-range – additive, general-purpose, gate v2 orchestration

[status: planned]

[verify] smoke: (http-get url) returns status + body string; smoke: (http-download url path) streams response to disk, returns hash; smoke: (spawn argv) runs a subprocess, captures exit code + output; smoke: prims documented in lisp-interpreter chapter and seeded; details

gen-bridge

FUTURE EDGE: gen API submission (fal/Replicate/direct), job polling, take landing; expands library bindings into input_snapshot; local ComfyUI as later backend behind same interface

[status: planned]

> *[verify] smoke: edit/gen-submit expands cast/refs, writes input_snapshot, creates pending takes; smoke: poller lands done takes with media_hash + cost_cents; smoke: failed jobs mark takes failed with log tail; smoke: spend report sums cost_cents per project and cut; smoke: budget_cents cap blocks submission over budget; smoke: re-gen after asset appearance edit produces a new snapshot, not a silent reuse of the old lock; details*

ui

routes /edit, /edit/<slug>: cast/library panel, shot table with take picker, cut timeline view, render state, spend panel

[status: planned]

> *[verify] smoke: GET /edit 200 after load-library; smoke: project page lists assets/cast and shots in ord with chosen takes; smoke: binding a character to a shot shows on the shot row; smoke: choosing a take updates the cut and invalidates render cache visibly; smoke: spend panel shows cost totals per backend*

agent-access

pp_eval edit/? as the API; agents drive library, cast, gen, and cut loops

[status: planned]

> *[verify] smoke: pp_eval edit/asset-upsert, edit/shot-cast, edit/expand, edit/choose, edit/render work; smoke: an agent can fork a cut branch, retarget cast, swap a take, and render; smoke: an agent can promote a take into a character primary ref*

31 borge/jobs.borg

pricklypear-jobs

Pricklypear book chapter: jobs – durable background jobs, step checkpoints, and cron; host owns concurrency, guests see rows

[status: implemented]

– *agent note:* 2026-12 plan pass: flipped planned -> implemented. All four deliverable subsections (node-shapes, runner, step-checkpoints, schedules) are implemented and live: image/lib/jobs.ml (5-field cron + every-ms, SKIP LOCKED claim, runner fiber forked in boot.ml), prims_db.ml registers submit-job/submit-job-at/job-status/cancel-job/jobs/schedule/unschedule/schedules. The label lagged the ship.

jobs

Durable jobs as typed data nodes; a host-owned runner fiber; step checkpoints for exactly-once; schedules for cron. The async story for Nopales is job-shaped, not call-shaped.

[status: implemented]

==========

WHY THIS CHAPTER EXISTS ==========

A web framework needs background tasks and cron. AI calls take minutes; renders take longer; backups and feed polls must happen with no request in flight. Today every such feature would hand-roll its own deferral, and the book already carries three fragments of the same idea: film-edit's job-first vocabulary (gen-submit / gen-status), image.primitives-layer's deferred "host cron/scheduler table", and one-tree's user-keyed data placement. This chapter is THE async substrate: one design that those surfaces build on.

The shape is dictated by decisions already made: - ONE IMAGE PROCESS – the worker is an in-process host fiber, not a fleet. No broker, no Redis, no worker tier (the Celery shape is a symptom of stateless web workers; we have the opposite constraint). - THE TREE IS TRUTH – jobs are typed data nodes, not rows in a queue table. Inspection, backlinks, provenance, and /data browsing come free. (SUPERSEDED – see the node-shapes reconcile note: v1 ships a DEDICATED jobs table, migrations/015_jobs.sql, not tree nodes. Kept here as the original plan's rationale; the dedicated-table design below records why the implementation diverged.) - HOST OWNS CONCURRENCY – Nopales has no fiber/async API and gains none. Guests submit jobs and read job rows; the host runner fiber calls back into eval through the same Control rim an HTTP request uses.

==========

THE MODEL: CALLERS AND CALLEES ==========

Eval is always direct-style and request-shaped. What varies is WHO CALLS:

HTTP request ?? REPL line ???? Control.perform_prim ?? rim (Eio fiber) runner fiber ?? (one-shot effect) does the I/O

The runner fiber is a third caller into the same dispatch. From a job function's perspective a job run is indistinguishable from someone hitting a route: same prims, same budget accounting, same with-transaction semantics. No guest-visible suspension exists at any point in this design.

==========

NODE SHAPES (one-tree placement – RECONCILED 2026-08) ==========

RECONCILE: the implementation ships a DEDICATED table, not tree nodes. migrations/015_jobs.sql + image/lib/jobs.ml + the boot-time runner fiber (image/lib/boot.ml) deliberately chose a dedicated 'jobs' table (plus 'job_steps' and 'schedules') over tree_nodes/data.shared.job.* for three reasons, per the 015_jobs.sql header comment: 1. SKIP LOCKED CLAIM PROTOCOL – the runner's due-scan ('UPDATE ... WHERE status='pending' AND run_at<=now

ORDER BY run_at FOR UPDATE SKIP LOCKED LIMIT 1') needs real typed status/run_at columns and a partial claim index (jobs_claim_idx ON jobs(run_at,id) WHERE status='pending'). A matpath subtree scan over data.shared.job.* cannot drive that partial index and would force a tree walk per claim's ORDER-BY. 2. KERNEL AUTHORITY – migrations are the git-source-of- truth kernel tier (AGENTS.md branching authority); job rows are kernel state, so they belong to a migration table, not a branch-lens Nopales type. 3. STRONGER BRANCHING EDGE – with a dedicated table (and no branch id on the rows), fork/merge/promote STRUCTURALLY cannot copy, diff, or move a job – the 'NEVER participates in branch lenses' hard edge holds by construction, as originally intended. The tree-truth aspiration (inspection/backlinks//data browsing) is NOT met for jobs in v1: jobs are inspected via the job prims + /data is not a job surface. This is an accepted v1 tradeoff (kernel-backed queue state); a future projection onto tree nodes is possible but not planned.

The original tree placement (kept for the decision trail):

job data.shared.job.<id> job-step data.shared.job-step.<job-id>.<step-name> schedule data.shared.job-schedule.<name>

Shared placement was deliberate: the runner (host identity) must claim and mutate job rows regardless of who submitted, and path-prefix confinement on data.u.<user>.* would make the runner a privilege exception. Visibility is enforced at the PRIM layer instead: (jobs) and (job-status id) confine to the caller's submitted_by unless the caller is admin – same rule the notes garden applies to its shared indexes. submitted_by / branch / run_at are set at submit time and are NOT updatable through the CRUD prims (the runner owns status transitions).

job fields (migrations/015_jobs.sql): id uuid PK, gen_random_uuid at submit fn string name of a 1-arity Nopales fn args json single argument value branch string code lens captured at submit time submitted_by string user who submitted (visibility key) status enum pending | running | done | failed | dead run_at epoch-ms earliest start attempts int runs so far max_attempts int default 3; exhausted ? dead result json return value on done error string last failure message runner_id string image boot instance that claimed it created_at timestamptz submit time (list ordering)

job-step fields (checkpoint rows): job_id, step_name, value json, finished_at epoch-ms

schedule fields: name, fn, args, branch, cron string (5-field) OR every-ms int, next_run epoch-ms, enabled bool

========== GUEST PRIMS (the whole Nopales surface) ==========

(submit-job "fn" args) ? job-id; captures caller's branch + identity; run_at = now (submit-job-at "fn" args when) ? job-id; when = epoch-ms (job-status id) ? the job row (confined) (cancel-job id) ? pending ? failed/cancelled (jobs) ? caller's jobs, recent first (with-step "name" (lambda () body)) ? checkpoint boundary; inside a job: memoized by (job-id, name); outside a job: plain function call (NOTE: named with-step, not step – libs/rb already defines a 'step' recipe-DSL function; reserving the flat name 'step' for a kernel special form would clobber that library) (schedule "name" "cron-or-ms" "fn" args) ? upsert (unschedule "name") ? disable (schedules) ? list

Capability effects: submit/cancel/with-step are WriteDb; status/jobs/schedules are ReadDb; schedule/unschedule are WriteDb. Job FUNCTIONS carry whatever effects their bodies carry – inference + badges work unchanged because a job body is ordinary Nopales on an ordinary branch.

THERE IS NO await-job. Guests never block on a job; they poll rows (htmx fragment refresh in the browser, job-status in the REPL). Result delivery is pull, not push – the same vocabulary film-edit specified for gen/render.

========== THE RUNNER (host side) ==========

One Eio fiber forked at boot, beside the HTTP accept loop and REPL. Loop:

1. CLAIM – due jobs (status=pending, run_at <= now), oldest first, claimed with SELECT ... FOR UPDATE SKIP LOCKED + status?running + runner_id, committed before eval begins. SKIP LOCKED is correct from day one and is exactly the claim protocol an out-of-process worker (the Blender bridge shape) would run against the same rows later. 2. EVAL – resolve fn on the job's recorded branch, call it with args, under a synthetic request context (whoami = submitted_by, branch = recorded branch) – the same session record the REPL fabricates, no HTTP request involved. Standard eval budget applies. 3. RECORD – success ? status=done + result; exception ? attempts+1 and either status=pending with run_at = now + backoff(attempts), or status=dead when attempts = max_attempts.

WAKE-UP: sleep until min(run_at) of pending jobs, with a bounded poll interval (tunable, default seconds) as the floor so earlier inserts are never missed by a stale sleep target. v1 has no LISTEN/NOTIFY.

RECOVERY: each boot stamps a fresh runner_id. After claim and before new work, the runner fails jobs left status= running by a DEAD runner_id – they were mid-eval at crash – retrying them under the attempts/backoff rule. Single-image means the "fleet" is one fiber; runner_id exists so crash recovery is explicit instead of implied.

STEP CHECKPOINTS (the DBOS idea, Nopales-shaped)

A job that dies at minute 9 of 10 should not re-spend minutes 1-8. (with-step "name" thunk) is the boundary:

- First execution of (job-id, "name"): run the thunk, write the checkpoint row, return the value. - Re-execution (retry after crash): the checkpoint row exists ? return its value WITHOUT running the thunk.

Steps compose with with-transaction to give EXACTLY-ONCE for DB-writing steps, the DBOS co-location trick in our idiom: open one dynamic transaction, run the thunk (all its creates/updates ride the same connection), write the checkpoint row in the SAME transaction, commit. Either the writes and the checkpoint both land or neither does – the step provably never double-executes. The guest never sees a transaction handle; exactly-once is the default shape of (with-transaction (lambda () (with-step ?))), not a discipline.

Resume is by CHECKPOINT LOOKUP, not code replay: there is no determinism constraint on the job body. The one rule: a step name is a stable string within one job definition – (with-step "name" ?) enforces this syntactically. Job code is pinned at submit time (branch + fn name), so a redefine on main mid-job does not change what a running retry resolves.

v1 steps are RETRY-scoped: they shorten re-execution of a retried job; they do not suspend a live eval and resume it across boots mid-run. A crash mid-job restarts the job function from its top, replaying checkpoints.

SCHEDULES (cron)

Cron is sugar over the same machinery: a schedule row with next_run; the runner's due-scan treats due schedules like due jobs – submit the job, then compute the next next_run from the cron string or every-ms interval and write it back. One queue, one claim path, one recovery story. Missed fires while the image was down collapse to ONE catch-up run at boot (a backup that was down for three days runs once, not seventy times).

HARD EDGES (non-goals for v1)

- NO guest-visible fibers, promises, or await. Host owns concurrency; guests see rows. - NO in-image out-of-process isolation. A job that wedges in a blocking rim call can stall the image; eval budgets bound runaway Nopales, dead-runner recovery bounds crashes, and genuinely long external work belongs to an external worker speaking the same SKIP LOCKED claim (film-edit's Blender bridge is the precedent shape). - NO multiple queues, priorities, rate limits, unique-job

constraints. Single FIFO queue, at-least-once at the job level, exactly-once at the transactional-step level. - NO mid-job guest notification. htmx polling or job-status reads only. - Job state NEVER participates in branch lenses. Paths contain no branch id; fork/merge/promote structurally cannot copy, diff, or move a job (one-tree branching- interaction stands by construction).

========== RELATIONSHIP TO EXISTING CHAPTERS ==========
- film-edit: gen-submit / gen-status / render-job become applications of THIS substrate (a render job = a job row whose fn calls the Blender bridge); film-edit keeps its memoization-by-hash cache, which is orthogonal. - image.primitives-layer: the deferred "host cron/ scheduler table" is this chapter's schedule nodes. - one-tree: jobs are the first shared-NAMESPACE data type placed under data.shared.* by design; the placement and its prim-level confinement are specified above. - lisp-interpreter.effects: new prims join the prim ? effect-set table; nothing else about inference changes.

node-shapes

job / job-step / schedule rows in a dedicated migration table (015_jobs.sql): field contracts, runner-owned status transitions, SKIP LOCKED claim index; v1 is a dedicated table, not data.shared tree nodes (see details RECONCILE note)

[status: implemented]

> *[verify] build: dune build @all; test: image/test: jobs_test.ml node-shapes – job node create/claim/status transitions (submit?pending?claim running?record done/failed?dead) incl. runner-owned field confinement (submitted_by + branch pinned at submit; (jobs)/(job-status)/(cancel-job) confine to caller unless admin; cancel only pending and only yours); smoke: pp_eval '(submit-job ?)' ? (job-status id) shows submitted_by + branch pinned, then the runner fiber drives it pending?running?done with result (jobs are inspected via the job prims, NOT /data – v1 reconcile: no /data/job surface)*

runner

boot-time Eio runner fiber: SKIP LOCKED claim, synthetic request context, budget, attempts/backoff, dead-runner recovery at boot

[status: implemented]

> – *note:* 2026-12 ralph loop 19 (campaign 4.0 plan verify) found the runner ARGS bug: eval_job wrapped job.args with Printf.sprintf "%S" (boot.ml), so a jsonb NUMBER arg was evaled as a STRING literal -(submit-job "f" 1) stores args=1 but the runner evaled (f "1") -> Interp_error -> retries -> dead. Numeric/bool/object args all failed; only JSON-string args round-tripped. 4.1 FIXED it (Jobs.eval_src): job.args is the jsonb column rendered ::text = one JSON literal, spliced DIRECTLY as the call (never %S-quoted), so numeric/object/bool args eval as their real type, and the runner surfaces the REAL error text (pp_interp_error) instead of opaque Interp_error(_). ARG-ENCODING CONTRACT on submit: the submit-job VStr branch stores the raw string as jsonb (unquoted), so a string arg must already be valid JSON -(submit-job "f" "\"hello\"") for the string hello; align submit+runner on one encoding (prim surface + Jobs.eval_src + boot runner are consistent; see image/test/jobs_test.ml args-bug suite).
>
> *[verify] build: dune build @all; test: image/test: jobs_test.ml runner – claim skips locked rows (second-connection FOR UPDATE); exponential backoff requeues into the future / exhausted?dead; dead-runner reaper fails stale running rows (retry or dead) while leaving our own runner_id*

untouched; smoke: submit a job that sleeps, watch status pending?running?done with result via (job-status); smoke: submit a job whose fn raises ? attempts increments, retry, eventual dead; smoke: restart image mid-job ? stale running row recovered per attempts rule

step-checkpoints

(with-step "name" thunk) memoized by (job-id, name); with-transaction composition gives exactly-once for DB-writing steps; plain call outside jobs
[status: implemented]

[verify] build: dune build @all; test: image/test: jobs_test.ml step-checkpoints – job-id fiber binding (with_current_job_id scopes current_job_id_opt; null outside a job) + checkpoint memoization round-trip on job_steps (write reads back, upsert overwrites, per (job-id,name) key independent across step names and across jobs); smoke: two-step job killed between steps via forced retry: first step not re-executed (side-effect counter row stays 1)

schedules

cron/every-ms schedules as rows; due-scan fires by submitting a job + advancing next_run; downtime collapses to one catch-up run
[status: implemented]

[verify] build: dune build @all; test: image/test: jobs_test.ml schedules – cron next-fire computation (every-minute boundary, across-month Jan-1, impossible Feb-30 never matches) + every-ms drift/interval + spec classification (integer is not cron) + schedule CRUD/claim/advance/disable lifecycle on the schedules table; smoke: pp_eval '(schedule "t" " * * * *" fn args)' ? runner fires a job within a minute; (schedules) shows advanced next_run; smoke: disable via (unschedule "t") ? no further submissions*

non-goals

no guest async/fibers/await; no fleet control plane; no multi-queue v1; out-of-process workers via shared claim protocol only
[status: planned]

[verify] test: conformance: no Nopales binding exposes await/promise/fiber (surface lint over prim table)

32 borge/forge.borg

pricklypear-forge

Pricklypear book chapter: forge – executable spec graphs; borge's workflow as habitat data. LLMs draft and review; mechanical checks flag anomalies; the human gates each level of the descent.

[status: planned]

> – *agent note:* Design rationale, from the 2026-08 conversation that produced this chapter: - "Procedural borge": the spec stops being a document you consult and becomes a program you run. Phase transitions are driven by code, not by a human typing plan/make/review. - Victory conditions are the artifact; code is a cache. If codegen trends free, the expensive scarce thing is the VERIFIED SPEC GRAPH – every node carrying its win condition, provably green. Code is re-derivable output of the graph. - The frontier is computed, not judged: free-vars over drafted bodies derives what is missing; build order is a topological walk, not an LLM guess. - Mechanical flags first, judgment as residue: capability escalation, missing victory condition, dangling refs, cycles, orphans – all computable. The human reviews a list of anomalies, not a wall of nodes. Review fatigue is the quiet killer of every human-in-the- loop system; the defense is surfacing LESS over time, not more. - Human gates each level of the tree descent. Mistakes get cheaper as you go down; attention is allocated top-heavy because blast radius is top-heavy. Progressive disclosure of commitment: you are never asked to review more than one delta of abstraction at a time. - The loop lives IN the habitat (a Nopales package), not in the laptop harness. Separation of powers: drafter and driver must not be the same mind. The harness agent is demoted to drafter; the human answers the loop via the flag queue, does not drive it. - Reroll is INFORMED: reroll-with-note attaches a constraint to the node; accumulated constraints are a durable style guide the drafter cannot drift from. Otherwise reroll is a slot machine. - UI LAST, on evidence: you cannot design the approval UI until you know which flags actually fire in practice. The boring anomaly queue beats the gorgeous graph explorer. Build the loop headless; the queue teaches you what to draw.

forge

Executable spec: the borge discipline as a living graph of typed nodes in the habitat. A spec is a tree; each node carries a machine-checkable victory condition; LLM drafters fill leaves bottom-up along a computed frontier; mechanical checkers flag anomalies; the human approves each level before the descent continues.

[status: planned]

==========

WHAT THIS CHAPTER IS ==========

Borge today is a CLI over .borg FILES. This chapter is the same discipline re-expressed as HABITAT DATA: the spec is a tree of typed nodes, the workflow is a Nopales interpreter loop running inside the image, LLM calls are drafting and review passes over nodes, and the human's plan/make/review commands become gates the loop waits on. Nothing about the trust model changes: the human promotes, the human gates, mechanical checks run before any judgment is asked for.

The package is libs/forge – pure Nopales, product-shaped, living on branches like every other product lib. It gains ONE new kernel prim (forge-effects, be-

low) and reuses everything else: tree nodes, data rows, branching prims, the ai-authoring LLM surface, the jobs runner, and the notes/log/docs conventions of habitat-workflow.

THE GRAPH (node shapes, one-tree placement)

A spec graph is a set of typed data nodes. Per one-tree, code-side nodes live under the branch lens; graph STATE (status, review verdicts) is shared data, keyed by owning user, under data.shared.forge.* – same placement argument as jobs: the loop (host identity) must mutate node rows regardless of who is drafting.

forge-node data.shared.forge-node.<graph>.<path> forge-flag data.shared.forge-flag.<node-path> forge-graph data.shared.forge-graph.<name>

forge-node fields: graph string owning graph name path string "root/auth/login" – position in tree kind enum requirement | module | function | test title string one-line purpose (human-readable) body string Nopales source when kind=function; else "" verify string Nopales source of the victory check effects string declared badge (pure|read-db|write-db|?) status enum planned | drafted | verified | flagged | approved | implemented constraints json accumulated reroll-with-note strings parent string path of parent node ("" for root) children json list of child paths (denormalized index) branch string code lens this node was drafted on author string whoami at last mutation target string existing binding this node modifies ("" for greenfield; when set, the drafter is given the binding's current source as context and verify may run a regression) test-fn string existing test binding to run as a regression after install ("" disables; when set with target, verify-node installs the drafted body as the target binding, calls test-fn, restores)

forge-flag fields: node_path, check (enum: capability|victory|dangling|cycle|orphan|size|judgment), detail string, resolved bool, resolution string ("" until a human or the loop closes it)

forge-graph fields: name, root_path, status (planning|descending|verifying|done|stalled), created_by, created_at

The DENORMALIZED children index exists because backlinks over body strings is the wrong query; children must be enumerable without parsing. parent is the canonical link; children is maintained by the same mutation fns (one transaction).

THE FRONTIER (planning is a computation, not a judgment)

The single strongest idea in this design: build order is DERIVED FROM CODE, not guessed by an LLM.

free-vars: walk a parsed body; collect symbols that are not bound by any enclosing lambda/let/define and are not kernel prims or existing bindings. unresolved: free-vars filtered against bound names. frontier: all planned nodes whose unresolved set is empty – leaves whose dependencies all exist. stub-children: when a draft's free-vars reference names that exist NOWHERE (not prim, not binding, not a sibling node), those names become NEW planned child nodes. The drafter invented a helper; the graph records the debt.

Bottom-up falls out: a node can only be DRAFTED when its dependencies are all at least drafted. The frontier is recomputed after every mutation. There is no planner prompt; there is a graph query.

Cycles: if drafting A produces a stub B whose drafting references A, the cycle check flags it. Recursion is fine in Nopales but breaks the topological frontier – a cycle means the level needs restructuring (mutual-recursion node, or a declared base-case split), and that is a HUMAN decision, so the flag goes to judgment.

MECHANICAL FLAGS (checks that run before the human wakes)

Each flagger is a small pure-ish function over the graph. They run after every draft and after every level-descent proposal. The approval surface shows

FLAGS, not nodes.

capability child's inferred effects (via forge-effects prim) exceed the parent's declared badge. "read-only view" containing (create ...) is caught here, not by eyeballing. victory node has empty verify source. Unapprovable by definition; flagged before human sees it. dangling free-vars reference nothing: not prim, not binding, not a sibling/parent node. Either a missing stub or a typo'd name; both worth a flag. cycle frontier math found a dependency loop. orphan node traces to no requirement ancestor. Gold-plating detector: completeness means every requirement has a node AND every node traces to a requirement; no orphans either direction. size drafted body exceeds a review-in-one-glance threshold (default ~20 forms). Suggests a split; not a hard error. judgment the drafter itself asked for clarification. The "flag for review/clarification" of the tri-state review. This is the log/issues escape hatch, node-scoped.

The one new kernel surface:

(forge-effects "name-or-src") ? badge string Runs lisp/lib/effect.ml infer over the named binding (or parsed source) and returns EffSet.badge. This is the SAME analysis install-function already gates on; this prim merely EXPOSES it. Read-only, Pure effect.

THE LOOP (the interpreter that replaces plan/make/review)

One function, forge/step, is the whole state machine. It is deliberately boring:

(forge/step graph-name) 1. If unresolved judgment flags exist ? do nothing; the loop is BLOCKED on the human. Return the flag list. (The human's queue IS the control flow.) 2. Else if the current level has unapproved nodes ? run mechanical flaggers, present the level for approval, stop. HUMAN GATE. 3. Else if the frontier is non-empty ? pick one node, assemble a draft prompt (context: title, parent declaration, constraints, sibling summaries, the platform-ref note), call the drafter (agent-session + agent-say, or llm-seed for leaf functions), parse the result into body+verify, run mechanical flaggers, write the node. Return what changed. 4. Else ? the level is complete; propose the descent (stub children of approved nodes) and stop. HUMAN GATE on the new level.

forge/run is forge/step in a job, so the loop persists across HTTP requests and survives the laptop disconnecting. The jobs chapter supplies the fiber; forge supplies the step function. One job per graph, re-submitted after each step while status is not done/stalled.

TRI-STATE REVIEW: when a node's draft passes mechanical checks it goes to LLM review (a SECOND agent session, not the drafter's) which returns approve | deny | flag. Deny ? redraft with the review note appended to constraints. Flag ? judgment flag, human queue. Approve ? status verified (verify source passes) or stays drafted (verify needs a human run). Separation of powers is structural: drafter, reviewer, and driver are three different sessions.

REROLL-WITH-NOTE: the human's reject carries a reason. The reason appends to the node's constraints, and every subsequent draft prompt includes all constraints. The graph accumulates taste; the drafter cannot drift from a constraint it has been given twice.

THE HUMAN SURFACE (triage, not review)

v1 is deliberately minimal – the UI is deferred on PRINCIPLE (you cannot design the approval surface until you know which flags fire). Phase one surfaces:

/forge list graphs + status + open flag count /forge/<name> one graph: current level's nodes with flags, grouped by flag type; approve / reroll(with note) / veto per node; approve-all-clean button log/issues judgment flags land here too, one line each, per habitat-workflow

The approval page shows ANOMALIES. A node with zero flags and a passing verify renders as one line: title, badge, approve button. A flagged node renders its flag detail first. The human reads flags, not code, unless they choose to expand. This is the review-fatigue defense: the loop surfaces LESS over time, not more.

LEVEL GATE SEMANTICS: approving a level means every node at depth N is status>=approved and every flag at depth N is resolved. The loop will not draft depth N+1 until the depth-N gate passes. This is progressive disclosure of commitment: no one, human or LLM, evaluates more than one delta of abstraction at a time.

========== RELATIONSHIP TO EXISTING CHAPTERS ==========

- habitat-workflow: forge is the same discipline with the phases driven by code. Session ritual, obituary rule, file-don't-fix, and handoff notes are UNCHANGED – forge graphs write spec/<pkg> docs on promote, exactly as a human session would. The notes docs remain the living spec; the forge graph is the WORK-IN-PROGRESS view. - ai-authoring: drafters use propose-function / llm-seed / agent-session per that chapter's provenance and badge rules. forge adds NO new privilege path; machine-authored code lands on a branch and promotes through the same human gate. The ai badge applies to every forge-drafted binding. - jobs: forge/run is a job. The runner fiber is the only place the loop executes; no new concurrency is added. - one-tree: node shapes and placement are specified above per one-tree.branching-interaction. Graph state never participates in branch lenses (same argument as jobs). - lisp-interpreter.effects: forge-effects exposes the existing infer; nothing about inference changes.

========== HARD EDGES (non-goals for v1) ==========

- NO graph-visualization UI. A tree list with flags is enough; the force-directed graph explorer is a later nicety, built on evidence of what the queue needs. - NO autonomous promote. The loop never calls promote; it prepares a branch and a spec doc. The human runs pp-sync / promote exactly as today. - NO drafter-is-reviewer. The same agent session never both writes and judges a node. - NO unbounded descent. A graph declares max-depth at creation; the loop stalls (status=stalled, judgment flag) rather than drafting past it. - NO rewriting of borge-the-CLI. .borg files remain the git-tracked source of truth for the KERNEL. forge is for PRODUCT code (libs/*) where the habitat IS the source of truth. The two coexist; forge does not eat borge.

graph-model

forge-node / forge-flag / forge-graph typed nodes: data.shared placement, denormalized children index, status enum, constraints accumulation; target + test-fn fields anchor modify-existing nodes

[status: implemented]

> *[verify] build: dune build @all; test: image/test: forge node create/update; children index stays consistent with parent links across edits; smoke: pp_eval '(forge/new-graph "x")' ? row at /data/forge-graph; (forge/add-child ?) maintains both directions*

frontier

free-vars over parsed bodies; unresolved filter; frontier query; stub-children on unknown refs; cycle detection flags loops

[status: implemented]

> *[verify] build: dune build @all; test: image/test: free-vars of (lambda (x) (+ x y)) is {y}; frontier excludes nodes with unresolved deps; test: image/test: drafting a body referencing undefined name 'helper' creates a planned child node named helper; smoke: cycle A?B?A surfaces a cycle flag, not an infinite stub loop*

mechanical-flags

capability escalation via forge-effects prim, missing victory, dangling refs, cycles, orphans, size heuristic – each a small fn over the graph; judgment is the

human escape hatch

[status: implemented]

> *[verify] build: dune build @all; test: image/test: forge-effects prim returns badge for a named binding (pure for +, write-db for create); test: image/test: child with write-db body under parent declared read-db raises capability flag; smoke: node with empty verify source is victory-flagged before appearing on the approval page*

loop-and-gates

forge/step state machine (blocked?flagged?draft?descend); forge/run as a job; tri-state LLM review with separate reviewer session; reroll-with-note constraint accumulation; level-gate semantics; verify-node evaluates the victory expression on the current branch session

[status: implemented]

VERIFY EXECUTION SEMANTICS verify-node evaluates (let ((fn body)) verify) via eval-string on the current branch session. The drafter seed already instructs verifies to create and clean their own test data, so a verify may touch the DB on the current branch; this is accepted for v1.

REGRESSION MODE (modify-existing nodes): when a node has both target and test-fn set, verify-node runs a regression after the primary verify passes. It saves the target binding's current source (function-source), installs the drafted body as the target binding (eval-string define), calls test-fn, and restores the original source. Because Nopales closures capture the session env by reference, the test function's calls to the target name exercise the NEW body. If test-fn returns truthy the regression passes; otherwise a judgment flag is raised. Restoration is best-effort: if the target had no source (a prim), verify-node skips regression and falls back to the primary verify only, with a judgment flag noting the skip.

Scratch-branch checkout (evaluating verify on an isolated dev branch) is a FUTURE hardening, not v1. The current design trusts the drafter seed's create-and-clean discipline and the separation-of-powers review to catch misbehaving verifies.

> *[verify] build: dune build @all; test: image/test: step with open judgment flags is a no-op returning the flag list; test: image/test: reroll appends the note to constraints; next draft prompt contains it; smoke: full descent on a toy graph: root ? level 1 approved ? stubs ? leaf drafted ? verified, all via forge/run job; smoke: loop refuses to draft depth N+1 while any depth-N node is unapproved*

existing-app-bridge

Bootstrapping and modifying existing code: forge/import-function reads a binding's source (function-source) and creates a node status=implemented body=source verify=(begin #t); the target field names an existing binding a node modifies, and forge/draft-prompt branches to include the current source as context; test-fn enables regression verify per loop-and-gates

[status: planned]

> *[verify] build: dune build @all; test: image/test: forge/import-function on a live binding creates a node status=implemented with the binding's source as body; test: image/test: a node with target set produces a draft prompt that includes the target's current source; smoke: import a small package's functions into a graph; frontier sees them as implemented; a modify-existing draft references the current body*

human-surface

/forge list + /forge/<name> anomaly-first approval page (approve/reroll-with-note/veto per node, approve-all-clean); judgment flags also land in log/issues; NO graph-viz, NO autonomous promote

[status: planned]

> *[verify] build: dune build @all; test: image/test: approval page groups nodes by flag type; clean nodes render one-line; smoke: browser: /forge shows a seeded graph; approving a node advances the level gate; reroll dialog accepts a note; smoke: a judgment flag appears in both /forge/<name> and the notes log/issues doc*

non-goals

no graph-viz UI v1; no autonomous promote; no drafter-is-reviewer; max-depth hard stop; borge CLI untouched – forge is for product code, .borg stays kernel truth

[status: planned]

> *[verify] test: conformance: no forge binding calls promote or merge (surface lint over the package); test: conformance: reviewer session id ? drafter session id on every tri-state review*

33 borge/habitat-workflow.borg

pricklypear-habitat-workflow

Pricklypear book chapter: habitat-workflow
[status: implemented]

> – *agent note:* 2026-08-02 status reconcile: libs/spec (~600 lines) + promote_soft_warnings in session.ml; live spec/todo+log/sessions+log/issues docs; /book/todo 200. Soft lint only (no hard bounce yet – intentional v1). /spec health 500 is runtime bug not missing package.

habitat-workflow

Spec-in-the-image: the borge discipline (spec -> build -> compare) as a habitat-native workflow, with promote as the goalpost-immobility gate
[status: implemented]

> *[verify] smoke: notes docs spec/<pkg> exist for at least one package and pass habitat lint queries; smoke: redefining a flow-listed public binding without a spec/decisions mention shows up in the drift report*

THE PROBLEM THIS CHAPTER EXISTS TO SOLVE

Package development on the habitat is agent-driven and session-based (phone REPL, pp_eval, browser). Without an artifact that outlives the turn, agents exhibit three failure modes:

1. Multiple happy paths through one workflow – nothing records which path was chosen, so each session re-derives "how this works" from the code, and code under-specifies that. 2. Redundant problems – no registry of known problems, so the same issue is "discovered" twice and fixed two incompatible ways. 3. Flip-flop rewrites – solving A with B's approach, breaking B, reimplementing A. Nothing records that the current shape was a DECISION WITH A REASON, so broken-looking code reads as "never wanted" instead of "wanted, currently broken."

File-borge suppresses these by forcing intent to exist as an artifact (the .borg book) that outlives the turn, and by gating edits so the agent cannot move the target while shooting at it. This chapter ports the DISCIPLINE, not the file mechanics.

THE CENTRAL MOVE: GATE THE PROMOTE, NOT THE REPL

File-borge gates keystrokes (plan/make file locks) because a working tree has no cheaper boundary. The habitat has a much better boundary already: the branch lens. So habitat-workflow gates the PROMOTE. Pre-commit hooks vs CI.

- The REPL stays playful and chaotic. Agents may thrash freely on user/personal and user/dev branches. - Nothing reaches system/main unless the comparison loop passes (spec-checks). - Promote (branching.promote) becomes pp's commit, and it grows a checklist. Review becomes looking at a page, not running a toolchain.

THE LITERATE INVERSION

In file-borge the book and the code live in different formats in different files, so a whole tool (balance / drift / report) exists to correlate them. On the habitat, spec docs, function docs, and code are ALL sexps in the same store under the same branching. So the book stops being a source artifact and becomes a VIEW: a spec doc's outline owns the narrative order; the referenced bindings fill in underneath via their function-doc and source. Drift stops being a report you run and becomes RENDERING: a chapter whose referenced binding was renamed shows a hole where the paragraph used to be. There is nothing to sync because the book route is a query.

RELATIONSHIP TO THE FILE BOOK

The OCaml kernel (image/, lisp/, migrations/) remains governed by THIS multi-file .borg book; git stays its source of truth. Habitat-workflow governs Nopales package code (libs/*, and their live counterparts on branches). Habitat spec docs are NOTES DOCS, so they branch like everything else: humans edit them on system/main; agents on branches propose changes via spec-issues and pending edits that the human accepts at promote time. The authorship-integrity rule file-borge enforces by lint ("agents never touch human comments") is here STRUCTURAL: spec docs live on main, agent sessions cannot write main, so the violation is impossible rather than detectable. pp-sync snapshot remains the durability/vault path for spec docs exactly as for package code.

spec-docs

One notes doc per package (slug spec/<pkg>): flows, canonical paths, decisions, status – the intent artifact that outlives the turn

[status: implemented]

> – *agent note:* 2026-08-02: convention + tooling live – (notes/doc/get "spec/todo") #t; spec/doc, flow-entries, flows-resolve in libs/spec. Coverage across all packages is ongoing content, not missing mechanism.
>
> *[verify] smoke: (notes/doc/get "spec/todo") returns a doc with flows/decisions sections; smoke: a spec doc's flow entries name existing function bindings (resolvable via function-doc)*

Every package that receives agent-driven development gets ONE notes doc with slug spec/<pkg>. It is short and structured, not prose-heavy:

FLOWS The user-visible workflows, numbered. Each flow names the ONE canonical path through the bindings, e.g. "add -> todo/create -> todo/render-row". New code paths must attach to a flow or create one – this is what kills multiple-happy-paths.

DECISIONS An append-mostly log of non-obvious choices WITH REASONS ("render is a pure function of the row so htmx swaps stay dumb"). This is the flip-flop killer: the next session can distinguish "wanted, currently broken" from "never wanted."

STATUS One line per flow: works / half-built / broken.

Spec docs live on system/main (shared intent). Branch lenses mean an agent CAN fork a spec doc onto its branch to draft a proposal, but promote of spec docs is a human-visible, human-approved step (see spec-checks). Function-level docs (define docstrings, lisp-interpreter.define-docstring) are the per-binding layer; the spec doc is the per-package narrative layer. A function-doc entry SHOULD reference its flow number(s).

session-ritual

The agent-facing protocol: branch-scoped work, obituary rule, file-don't-fix, handoff – recorded in the live agents note

[status: implemented]

> *[verify] smoke: (notes/doc/get "agents") contains the session-ritual rules (obituary, file-don't-fix, handoff); smoke: log/issues and log/sessions notes docs exist and accrete entries*

The durable agent guide is the notes doc with slug agents (advertised in /agent.txt); habitat-workflow adds these rules to it. All are notes-doc mechanics, zero kernel work:

1. WORK ON YOUR BRANCH. Agent sessions define/route on <user>/personal or a session dev branch, never directly on system/main. End of session: diff the lens (which bindings did I touch?), self-review against the declared flows, promote or revert.

2. NO SILENT REVERSALS (the obituary rule). An agent may not replace or delete an existing implementation without first writing its obituary in the spec doc's decisions section: what it was, why it existed, what changed in the world that invalidates it. Writing the obituary forces the agent to notice it is flip- flopping; half the time it will realize the old approach was right and something ELSE is broken.

3. FILE, DON'T FIX. Out-of-scope discoveries go to the log/issues doc, one line each, instead of expanding session scope. This is borge issue new for the habitat – and since notes docs are data, it needs no gitignored directory.

4. HANDOFF NOTE. Session ends with ~3 lines appended to log/sessions: what changed, what is half-done, what was deliberately NOT done. Flip-flop mostly happens ACROSS sessions, when the next session cannot tell half-built from broken.

Enforcement is by instruction (agents note) first; mechanical checks (spec-checks) make violations visible rather than relying on agent virtue.

spec-checks

Promote-time comparison: spec->code resolution, code->spec acknowledgment, doc coverage – promote grows a checklist

[status: implemented]

> – *agent note:* 2026-08-02: spec/lint + promote-checklist + Session.promote_soft_warnings wired into promote_to_main and branches UI (soft, non-blocking). Hard bounce graduation still future; matches "starting as soft warnings".
>
> *[verify] smoke: promote preview lists flow bindings that fail to resolve on the source branch; smoke: promote preview lists public bindings redefined on the source branch with no spec/decisions mention; smoke: promote preview lists public bindings with empty function-doc*

Promote (branching.promote) is the commit of the habitat; this subsection hangs the comparison loop on it. Before upserting, promote (or its preview UI) runs three checks against the source branch and the package spec doc, and reports – starting as soft warnings, graduating to bounces for admin-into-main promotes:

1. SPEC->CODE: every flow in spec/<pkg> names its canonical bindings; they MUST all resolve on the source branch. This is borge drift, but exact – sexp references, not grep.

2. CODE->SPEC: every PUBLIC binding redefined on the source branch is mentioned somewhere in the spec doc or its decisions section. Redefining todo/render without a spec acknowledgment bounces. This is the anti-flip-flop tripwire: the mechanical form of the obituary rule.

3. DOC COVERAGE: promote refuses undocumented PUBLIC bindings (empty function-doc). define stays loose – docs are not an ABI change, they are a shipping requirement. Undocumented is fine on your branch, unshippable on main. Docs get written at the moment of "this is real now," which is also the moment the agent can best explain what it built and why.

"Public" = bindings referenced by routes or by other packages (the surface a consumer can name); internal helpers are exempt. SPEC DOC CHANGES travel through promote too, and are shown to the human explicitly ("this promotion also modifies spec/todo – accept?"). Friction, not locks: one tap to approve; the agent can never silently ratchet the goalposts.

DEPENDENCY NOTE: checks 2-3 want define's persist path to be synchronous enough that the check sees the write (the fire-and-forget persist race must be fixed first; .borge-bugs). A phase check that races the write is theater.

book-view

The literate inversion: spec doc outlines own narrative order; bindings inline underneath – drift becomes rendering

[status: implemented]

> *[verify] smoke: GET /book/todo renders the spec doc outline with referenced bindings' doc + source inlined; smoke: a spec doc referencing a renamed binding renders a visible hole instead of stale prose*

A route /book/<pkg> (private) renders the spec doc as a chapter: walk the outline; at each flow or binding reference, inline the binding's function-doc and source (both are sexps in the same store). The book is a query, so it is ALWAYS current – the thing Knuth wanted and files could never quite give.

DRIFT AS RENDERING: a reference that no longer resolves renders as a visible hole in the page (styled, obvious), not as a line in a report. The book physically shows its own staleness.

This complements, not replaces, the file book: the OCaml kernel's chapters remain .borg files. /book serves the Nopales package layer. Whether the two ever merge into one rendered volume is an open question, explicitly not decided here.

spec-health

Habitat health page: packages x (flows verified, doc coverage, drift holes) – borge report as a browser page

[status: implemented]

> *[verify] smoke: GET /spec lists every package with a spec doc, its flow resolution status, and doc coverage*

/spec is the habitat's standing health page (private, admin): one row per package that has a spec doc – flows resolving / broken, doc coverage count, count of drift holes in /book rendering, last promote. This is borge report for the image, sized for a phone screen: review becomes LOOKING AT A PAGE.

Discovery contract: describe / apropos-docs surface doc coverage alongside results ("todo: 14 bindings, 3 undocumented"), so the gap follows the agent around instead of waiting for a report run.

non-goals

What habitat-workflow is NOT

[status: implemented]

- NOT a port of borge-the-tool into Nopales. No balance, no parse, no lint pipeline; the store is the parser. - NOT kernel governance. OCaml/migrations stay under the file book and git, full stop. - NOT REPL gating. No plan/make modes on eval, no dynamic-extent phase locks on define. Play is unrestricted on branches; the gate is promote. - NOT a rewrite of branching.promote's data model. This chapter adds checks around the existing selective-upsert mechanism. - NOT mandatory for every package. One-off garden scripts and personal-branch experiments never need a spec doc. Spec docs are for packages with multiple agent sessions of history – exactly where the three failure modes bite. - NOT provenance/audit of AI-authored code – that is ai-authoring.provenance. This chapter consumes author info but defines no new attribution model.

> – *agent note:* 2026-08-02: documentation-only; marked implemented as spec-complete.

34 borge/habitat-book.borg

pricklypear-habitat-book

Pricklypear book chapter: the spec IS the book – borg chapters rendered beautifully to paper AND to the habitat, with live code examples

[status: implemented]

> – *agent note:* 2026-08-30 top-level smokes verified: index order + /book/chapter render + reader suppression (loop 17), run-button click-eval (loop 18), book/verify hole render (scripts/smoke_book.py), export/print order parity (borge loop 12). course-documents verified 2026-08-31 (P3.1, loop 23) – /book/course/cs-interpreters + the compose-never-copy smoke; all five top-level smokes now hold.
>
> – *agent note:* 2026-08-29 authored from the cs-curriculum design session (docs/cs-curriculum.md). Probe of ‘borge book print .‘ on the post-pivot tree: chapters land p788+ in readdir order, inline not honored, libs/*.pp + migrations/*.sql absent. This chapter specced before any implementation; borge repo workstream described in .borg-workstream below.

habitat-book

One spec, two projections: borg files stay the source of truth; borge renders them to paper; the habitat renders them to live, evaluable pages. Courses are compositions over chapters, never copies of them.

[status: implemented]

> *[verify] build: dune build image; smoke: (load-library "book") then GET /book shows borg chapter index; smoke: GET /book/chapter/philosophy renders doc prose with statuses suppressed in reader mode; smoke: nopales example block renders with a run button; clicking evals in the reader's session and shows the result; smoke: book/verify re-evals all nopales examples in a chapter; a stale expected value renders as a hole; smoke: borge book export emits the same chapter order as borge book print*

WHY

The borge book is the spec AND the intended CS textbook (docs/cs-curriculum.md). The paper pipeline renders files, not the literate tree: post-pivot chapters print on p788+ in readdir order, the Nopales product layer and SQL never appear, and clone history changes your book's TOC. Meanwhile the habitat has /book (spec docs, package layer) but the .borg chapters – the actual course readings – are not on the habitat at all, so no agent, flashcard, or route can reach them.

Five decisions (all locked unless reversed with an obituary in spec/<when ported>):

1. THE SPEC IS THE BOOK. No forked textbook document. If a chapter is unreadable as teaching prose, the chapter is wrong – write it better. Register is a RENDER MODE (workshop: statuses/verify/agent-notes visible; reader: suppressed), not a document fork. Drift stays visible (holes), workflow scaffolding stays toggleable.

2. GIT STAYS AUTHORITATIVE for .borg. Habitat is a READ- PROJECTION (seeded rows) of chapter content. Edit-in- habitat (chapter editing, marginals, propose-a-patch) is a v2 question, explicitly deferred – same reserve as habitat-workflow.book-view's "two books merge" line, now upgraded from open question to named v2.

3. ONE PARSER, TWO PROJECTIONS. borge (lib/lang) remains the only parser of .borg. ‘borge book print‘ and the new ‘borge book export‘ share

one inline-aware ordered walk and one example-fence convention; paper and habitat can never disagree about chapter content or order.

4. HABITAT-FIRST EVAL. The course teaches by running code, and the habitat is the natural runtime for Nopales examples: read-time eval in the reader's session, render-time verification over the whole book. OCaml examples are capture-at-render-time only in v1 (borge runs the build harness; habitat displays block + captured output; no live OCaml evaluator – a later substrate decision, not a prerequisite).

5. COURSES COMPOSE, NEVER COPY. A course is a typed outline document that ORDERS chapters (front matter -> chapters -> labs) and references them; a chapter lives in one place and appears in many courses. Per-course paper = a course root borg file consumed by the same two projections.

export-projection

borge-side render stream: ordered inline-tree walk, reader/workshop modes, JSON/sexp export artifact – the habitat's feed and the paper's spine

[status: implemented]

> *[verify] smoke: 'borge book export .' writes <stem>.book.json with chapters in inline order; smoke: export includes .pp package sources and migrations as code chapters; smoke: reader vs workshop mode differ only in scaffolding blocks; smoke: two fresh clones produce byte-identical exports (deterministic walk)*

BORGE-TOOL WORKSTREAM (lives in the borge repo; requirements authoritative here):

- INLINE-AWARE WALK. The root project's inline tree defines chapter order ('pricklypear.borg' -> borge/*.borg). Files not referenced by the walk sort lexicographically AFTER the inline tree (appendix), never readdir order. 'borge book print' takes '–root FILE' to select a subtree (course roots, single-chapter prints). - DETERMINISM. Byte-identical PDFs/exports across clones (probe showed readdir-order chaos; checksum the manifest). - TYPE COVERAGE. .pp (Nopales product layer) and .sql (migrations) become printable chapters. - MODES. reader (strip status/verify/agent-note scaffolding) vs workshop (today's everything). Mode is a render flag; both carry drift holes. - EXPORT. 'borge book export [DIR] -o <stem>' emits a JSON artifact: [{root, chapters:[{slug, title, nodes:[...], examples:[{lang, src, expected?}]}], code-chapters:[...]}]. Same walk as print. This artifact feeds the habitat loader. - EXAMPLE FENCES. doc-block convention (shared print/web): "'nopales / "'ocaml fenced blocks, optional 'expect =>' trailer line for verification. Parser extracts them into structured example records; prose keeps the raw text.

habitat-loader

seed the export into the one tree: chapters as typed nodes, refresh on release – reads then inherit branch/lens semantics for free

[status: implemented]

> *[verify] smoke: scripts/load-book.sh <stem>.book.json upserts book chapters without clobbering hand edits elsewhere; smoke: (load-library "book") renders an index from tree rows, not from files*

- Loader: release-time. public_artifacts/build-release run 'borge book export' and a small loader seeds chapter nodes (type 'book-chapter') under system/main. Additive upsert, same discipline as package seed (branching.seed-policy): never overwrite after manual edits land – book rows are seed, not live authority. - Shape: one node per borg SECTION/SUBSECTION (title/body/status/mode-flags), one per code chapter (path + source), one per example (lang/src/expected). Children ordered by the export's inline order – the tree's ordering semantics carry the book's chapter order (tree-time). - Offline dev:

loader refreshable by hand (scripts/load-book.sh); habitat never require borge at runtime.

web-renderer

Nopales package ‘book‘: /book index of borg chapters + package specs; /book/chapter/<slug> pretty-printed with references, example blocks, reader/workshop toggle
[status: implemented]

> – *agent note:* 2026-08-30 all four smokes verified. Loops 17+20: /book index lists the 34 borg chapters in export order + the spec + code corpora; chapter pages render headings/prose/sections from tree rows; reader strips statuses + verify blocks, workshop shows both. Loop 23 (P3.1): \"course groupings\" verified – /book lists the Courses section (notes kind=course via tree/find-by) and a second throwaway course renders the SAME chapter by reference with zero tree duplication. Kernel delta rode along in P2.2: prose-tokens/render-tokens one-scan prims + string-split promotion (budget, see libs/book obituary).
>
> *[verify] smoke: GET /book lists chapters in exported order with course groupings; smoke: chapter page renders headings/prose/code/examples from tree rows; smoke: binding tokens in prose link to /binding/<name>; missing ones hole-red; smoke: ?mode=workshop shows statuses and verify blocks; default hides them*

- ROUTES. /book becomes the index of BOTH corpora: borg chapters (new) and package spec docs (existing spec/book-page). Borg chapters at /book/chapter/<slug>; package docs keep /book/pkg/<pkg> alias of current /book/<pkg> behavior (kernel fallthrough preserved; no breakage of habitat-workflow.book-view smokes). - SURFACE. pure-html + the ui/layout package; headings and prose from section nodes, code chapters as syntax blocks, examples as runnable blocks (eval-examples below). Elegant + phone-honest before clever: print-considerate CSS is a free paper fallback until borge course roots land. - REFERENCES. reuse spec-book-page’s binding inline+hole machinery for tokens found in prose – the drift renderer is already proven; the borg book inherits it. - MODES. default reader; workshop via ?mode=workshop or the /book UI toggle. The toggle IS the "spec vs textbook" argument made tangible.

eval-examples

read-time eval of nopales example blocks in the reader’s session; restricted prim table; (book/verify) as the book’s self-test
[status: implemented]

> – *agent note:* 2026-08-30 all three smokes verified: POST /book/eval-example returns value + elapsed and the run button is live (loop 18); define refused at the static gate, create/delete refused via known_fn capability, tree/upsert fails closed at the restricted rim; (book/verify) hole mechanics proven by scripts/smoke_book.py on a smoke_verify chapter – fail, refusal, and fix-forward all hole – and whole-book verify is green at the current 0 real example fences. Example fences in the .borg chapters themselves remain unwritten (authoring work, not machinery).
>
> *[verify] smoke: clicking a nopales block evals it and renders value + elapsed; smoke: blocks cannot define/persist: define/route/create prims are absent from the example table; smoke: (book/verify "philosophy") re-evals every block; mismatched ‘expect‘ shows as a hole row*

- PRIM. new kernel prim ‘(example-eval src)‘ (name bikeshed): parses + evals a nopales source string in a RESTRICTED environment: pure prims + read-only DB prims whitelisted; mutation families (define/route/checkout/create/update/ delete/create-user) absent. Runs in the reader’s branch env (visible defs bound, thunks forceable) so examples can touch real functions. Timeout + step cap (recursion/ complexity guardrails already exist in lisp/). - READ-TIME DEFAULT, AUTHOR-TIME VERIFY. Clicking runs in the reader’s session – habitat-first eval, the course property the design requires. ‘(book/verify [book?])‘ re-runs all blocks with ‘expect‘ trailer lines and reports holes; that is the book’s ‘dune runtest‘, and hooks into the habitat smoke suite (scripts). - OCAML BLOCKS. rendered as block + captured output from the borge export (captured at render time by the build harness there); inert buttons in v1, honest label "captured, not live".

course-documents

courses as typed outline documents over chapters: front matter, ordered chapters, lab nodes – compose, never copy

[status: implemented]

> – *agent note:* 2026-08-31 both smokes verified by scripts/ smoke_book.py section 8 on the local dev image: course doc course/cs-interpreters renders /book/course/cs-interpreters with the ordered reading list (document order asserted), chapter status badges from the seeded rows, front matter + labs sections, reader + workshop registers; a throwaway second course referencing the same chapter adds ZERO rows to data.book.ch – compose, never copy proven. Course root course/cs-interpreters.borg (repo) exports the 4-chapter paper via borge book export/print –root; the canonical walk excludes course/ roots (borge 9c1d52e). Renderer notes: reading nodes reference chapters by a ‘chapter: <label>‘ first body line; unresolvable refs render as holes; kernel count is VList-strict so the run length uses book/course-len (kernel issue filed in log/issues).
>
> *[verify] smoke: course doc ‘course/cs-interpreters‘ renders its ordered reading list with chapter status badges; smoke: same chapter renders inside two courses without duplication in the tree*

- A COURSE IS A NOTES/OUTLINE DOCUMENT (‘course/<slug>‘), typed kind, whose nodes reference chapter slugs in order, plus front-matter and lab nodes. Renderer /book/course/<slug> assembles it; the chapter itself never moves. labs link habitat objects (packages, issues, /repl snippets). - PAPER HANDOFF. a matching ‘course/cs-<n>.borg‘ root in the repo re-selects the same chapters for borge ‘–root‘ printing; the export honors it identically, so /book and the PDF stay cousins by construction, not convention.

out-of-scope-v1

what this chapter does NOT attempt in v1

[status: planned]

- Editing borg chapters from the habitat (write-path; v2 question alongside the deferred two-books-merge). - Live OCaml execution in the habitat (captured output only). - Marginia/annotations synced between paper and habitat. - Migrating spec/<pkg> package docs INTO the borg corpus (they stay their own corpus; /book indexes both). - Public access: /book stays private; public release is the existing /book.pdf face + its reader-mode flavor.

35 agent/bin/main.ml

```
(** glochid -- local-first Nopales-native agent harness (borge/agent.borg).

    v0.0 surface: stdin REPL. `agent` boots, loads ~/.config/agent/plugins/*.pp
    then ./.agent/plugins/*.pp, and enters a read/eval/print loop. Lines
    starting with `/` dispatch as plugin commands; lines starting with
    `(` are evaluated as Nopales; anything else is a prompt for the
    model.

    Flags:
      --mock-script FILE   canned provider replies (test/demo)
      --model NAME
      --base-url URL
      --once               run ONE full agent turn from piped stdin and exit
      -p EXPR              eval one Nopales expr and exit (pipe mode)

    Piped-turn mode: with either --once or non-tty stdin, the whole of
    stdin is read as the prompt (one string), a single full agent turn
    (model call -> tool calls -> final reply) runs, the final assistant
    text is printed, and we exit 0. This is the surfaces smoke #2
    trigger: `echo "say hello" | agent --mock-script m.json`.

36 agent/lib/http_ui.ml

```
(** glochid HTML primary surface (agent/lib; borge/agent.borg surfaces).

    A local HTTP server (Httpun_eio) bound to 127.0.0.1 (default port
    18090, --port to override; a busy port falls back to random). The
    chat + code browser pages are NOPALES-AUTHORED htmx
    fragments on the agent route table (rendered by Nopales via
    libs/html), dispatched in-process through [Runtime.dispatch_route].
    A chat/agent turn streams as multipart/mixed htmx fragments (one
    part per (html, HX-Target, HX-Swap)), emitted by OCaml; the fragment
    templates are Nopales (chat/user-bubble, chat/turn-open,
    chat/think-open, chat/think-token, chat/tool-open, chat/tool-line,
    chat/tool-done, chat/token, chat/error), so the surface is
    redefinable live. Each emitted part is
    also collected as data so a consumed turn replays through
    [hyper/stream] (surfaces smoke).

    Bootstrap/asset plumbing stays OCaml (per the surfaces scope): the
    vendored htmx + hx-multipart assets are baked into the binary
    ([Assets]) and served at /assets/*.js. *)

39 agent/lib/surface.ml

```
(** Agent Nopales surface (borge/agent.borg surfaces).

    The chat + code browser pages are NOPALES-AUTHORED htmx fragments on
    the agent route table, rendered by Nopales via [libs/html] -- NOT
    compiled OCaml pages and NOT vanilla-JS SSE. The surface is
    redefinable live (same env as plugins/REPL): re-evaluating a
    `(define chat/page ?)` at the REPL changes the next render without a
    restart.

    The multipart STREAM for a chat/agent turn stays OCaml (http_ui.ml):
    provider SSE ? delta assembly ? per-part (html, HX-Target, HX-Swap)
    frame + flush. Nopales owns the page skeleton + the fragment
    templates (chat/user-bubble, chat/turn-open, chat/think-open,
    chat/think-token, chat/tool-open, chat/tool-line, chat/tool-done,
    chat/token, chat/error); OCaml owns the effects-coloured stream and
    calls these templates per part.

    [load] boot-loads the embedded Nopales packages (libs/html, libs/hyper)
    then this surface source into the shared env, and registers the
    route-table routes (/, /code). *)

open Pricklypear_lisp

```
(** Pricklypear browser evaluator runtime.

    A js_of_ocaml build of the pure Nopales interpreter (lisp/lib) plus
    the shared pure-prims table (pure/prims_pure.ml). The same .pp
    package source the server serves is evaluated verbatim here -- see
    borge/structural-editing.borg client-eval.

    Built with `js_of_ocaml --effects=cps` (OCaml 5 effects require the
    CPS backend; the default backend fatally aborts). Exposes a small
    JSON-bound surface to JavaScript via [Js.export]:

      boot()                -> initializes the prim table + env
      load_source(string)   -> evaluates a multi-form .pp source string
      apply_op(string, json) -> runs a pure op fn over a JSON tree,
                                returns the result tree as JSON
      eval(string)          -> evaluates one Nopales expression,
                                returns its printed value (for REPL/debug)

    The pure prim table EXCLUDES every DB / IO / net prim -- the
    capability boundary IS the prim table. Wall-clock prims (now,
    date-today, date-weekday, etc.) are absent too: they live in
    image-only prims_time.ml because they read Unix. *)

(* Register the 5 CRUD primitives (get/create/update/delete/list) over
   `data_rows`. These are NORMAL prims: prim_fn = value list -> value.
   They return their real DB result -- e.g. (get 'user 42) returns the
   row's JSON fields as a VStr; `(mapcar (lambda (id) (get 'user id)) ids)`
   works.

   Per [one-tree.branching-interaction] /data DECISION: rows are
   USER-SCOPED. Creates land under the session user (author column +
   data.u.<user>.* tree path). Reads see only the caller's own rows
   plus shared seed types (bible-*, strongs-entry). Not branch-versioned. *)

62 image/lib/auth_throttle.ml

```
(** Pricklypear Image -- per-username login throttling (pure, in-memory).

    Brute-force resistance for password login (i-1787970741): a sliding
    window of failed attempts per (lowercased) username with exponential
    backoff once the window fills. Pure -- no DB: state is a bounded
    Hashtbl and the caller supplies the clock ([now] as a float), so
    behavior is deterministic and testable.

    Invariant: throttling engages ONLY after recorded failures. Fewer
    than [max_failures] failures inside the window always admits --
    verify_password runs on every Basic-auth request, so correct logins
    are never blocked. A success clears the key entirely.

    Single-domain: the image runs one Eio domain and these functions
    contain no effect points, so each call is atomic; no lock needed. *)

66 image/lib/crud.ml

```
(** Pricklypear Image -- CRUD primitives over the one-tree datum namespace.

    get/create/update/delete/rows are normal prims returning real DB
    results. They compose:
      (define u (get 'user 42))
      (str u)

    Per spec [one-tree.branching-interaction] /data DECISION (user-owned
    data) + [one-tree.migration-plan] (user-scoping):
      - Datum nodes live in tree_nodes; reads project through the
        tree_data_rows view. The scaffolding data_rows table is the
        reverse-mirror kept warm for residual readers / fork-copy.
      - Data is NOT branch-versioned (no branch_id); fork/merge copies
        code, not data.
      - Visibility is USER-SCOPED: a session sees rows it authored plus
        the shared seed corpus (bible-*, strongs-entry). Prim SQL
        enforces this; RLS on tree_nodes is the floor (migration 013).
      - `fields` is JSON; Lisp sees it as a string, with dict-* prims
        for field access.
      - No ORM; parameterized SQL via pgx. Multi-step atomicity uses
        Store.with_dynamic_transaction / (with-transaction ?).

    Uses [Io_lwt.Db.current_conn] so in-tx calls see the bound connection
    (read prims run inside with_transaction so set_local_pp_user keeps the
    RLS floor active; see i-rls-nontx).  Misses return VNil so Lisp can
    branch on `(if (get 'user id) ...)`. *)
open Pricklypear_lisp.Ast

(* Reads project through tree_data_rows (the tree_nodes datum view),
   UNCONDITIONALLY, with an explicit author/seed confinement predicate
   (primary control) plus the RLS floor on tree_nodes (migration 013).
   tree_data_rows is not behind the legacy PP_TREE_READS flag -- the tree
   view is the read source of truth. Writes go through Tree_store into
   tree_nodes directly; the reverse trigger mirrors tree_nodes back into
   the data_rows scaffolding table (residual readers / fork-copy). *)
let data_rel () = "tree_data_rows"

135 (** (select-for-update 'type id) -> VStr fields-json | VNil.
136     Reads ONE row by (type_name, id) AND locks it with SELECT ... FOR
137     UPDATE for the duration of the surrounding transaction.
138
139     Per spec [storage.transactions]: "Explicit row locks:
140     (select-for-update 'type id) Exposed as a primitive for finer
141     control."
142
143     MUST be called inside (with-transaction ...). Outside a dynamic
144     transaction this raises a clean Interp_error (User_error) instead of
```

```
    issuing FOR UPDATE on the pool conn -- which previously could poison
    Eio mutexes and cascade into auth failures (observed 2026-07-22). *)

              | _ -> VNil))

(** (create 'type "{fields-json}") -> VStr new-id; raises Prim_error
    ("create", "failed", "failed") when the insert is rejected.
    INSERTs a row with the given JSON fields, returning the new UUID.
    The author is the session's current username.

    Why take fields as a JSON STRING (not a Lisp value):
    - The Lisp layer doesn't yet have a dict/assoc value type.
    - Caller can build the JSON via (string-append ...) or a future
      (json ...) prim; for now both caller and DB speak JSON strings.
    - The DB validates it's well-formed JSON (jsonb column). *)

    (match id' with Some s -> VStr s | None -> VNil)

(** (update-field 'type id "field" "value") -> VStr id | VNil.
    Ergonomic shorthand for the v1 dict-set + update round-trip:
      (define u (get 'type id))
      (update 'type id (dict-set u "field" "value"))
    -> (update-field 'type id "field" "value")
    Composition is pure-OCaml (one get, one dict-set, one update inside
    this prim). Lwt-typed; returns VStr id on success, VNil if no row
    matched or no DB. Value is JSON-coerced (numeric strings emit as JSON
    numbers; non-parseable values emit as JSON strings -- same rules as
    dict-set).

    Runs in ONE transaction: the row is read with SELECT ... FOR UPDATE,
    the field merged in OCaml, and the UPDATE issued in the same tx. The
    FOR UPDATE lock serializes concurrent update-field calls on the same
    row, so two writers updating different fields both land (no
    lost-update race). The tx conn (with pp.user LOCAL set) is used
    throughout, so the RLS floor stays active. *)

(* (undo path [n]) -> restore the value at head-n as a NEW write at head+1.
   Restore-by-write (not head-pointer manipulation): the restore is itself a
   versioned append, so undo is lossless and redoable ((undo path) again on
   the restored state climbs back down the gen chain). Supports the datum
   path class (the first documented consumer is notes undo over datum
   nodes). For code paths restore-by-write is deferred to the code-restore
   consumer (consumers subsection) -- this prim reports that cleanly.
     Returns
   the written path or an error string. *)

(* ---- data lens operations (one-tree.borg branching-interaction,
   2026-08-23 make: versioned user-keyed data). A data lens is a
   deliberate fork of the user's live data.u.<user> subtree into
   data.l.<lens>.<user>. The lens can diverge (edits land in the lens,
   not live data), merge back (lens -> trunk, LWW per node v0), or be
   abandoned (drop the lens subtree). The default data.u stays
   single-head and branch-free; data.l is the explicit opt-in version
   axis. *)

(* (fork-data lens-name [type-name]) -> VStr.
   Copy the user's live datum nodes (data.u.<user>) into a fresh data
   lens (data.l.<lens>.<user>). When ~type_name is set, only that type
   is forked; otherwise all the user's non-seed types. Each source node's
   path is rewritten: data.u.<user>.<type>.<id> ->
   data.l.<lens>.<user>.<type>.<id>. The node payload (body, hash, author)
   is copied; the path field in the payload is updated. Returns
   "ok <lens> (<n> nodes)" or an error. *)

       VStr (Printf.sprintf "ok %s (%d nodes abandoned)" lens n))

(* (merge-data lens-name) -> VStr.
   Merge a data lens back into the user's live data.u.<user>. v0 policy:
   LWW per node -- the lens version overwrites the live version for every
   node in the lens. This is the simple, honest v0: no three-way diff,
   no conflict surfacing (the user deliberately forked, edited, and chose
   to merge; the lens is the intended new state). Conflict surfacing and
   three-way merge are the v1 ambition (one-tree.borg
     branching-interaction).

   For each lens node (data.l.<lens>.<user>.<type>.<id>), upsert the body
   into the live path (data.u.<user>.<type>.<id>), then CONSUME the lens:
   drop the data.l.<lens>.<user> subtree so the lens is gone after a
   successful merge (v0 lifecycle: fork -> diverge -> merge | abandon).
   The drop is explicit here, not left to the reverse mirror trigger:
   migration 023's tree_mirror_data_rows purge now skips data.l.* (so a
   lens survives ordinary live writes as a restore point), so merge owns
   the consume. Returns a JSON report {lens, merged, skipped, dropped}. *)

68 image/lib/example_eval.ml

```
(** Pricklypear Image -- restricted read-time eval for book example
    blocks (habitat-book.eval-examples).

    `(example-eval src)` parses + evals a Nopales source string so a
    READER can run a book's example blocks in their own session:

    - RESTRICTED PRIM TABLE. The example runs under its own Control
      rim whose table is a NAME FILTER of the caller's table: whitelist
      = Effect.pure_prims + Effect.read_db_prims + a reviewed
      read-only supplement ([read_extra_prims]). Everything else is
      ABSENT, and Control.perform_prim raises "unregistered primitive"
      on absent names -- fail-closed, including through function bodies
      and macro expansions (they eval under the same nested rim).
    - STATIC GATE. Before eval, each parsed form must (a) contain no
      mutation-family special form ([forbidden_special]) and (b) infer
      an effect set within {pure, read-db, html} via Effect.infer with
      known_fn from the branch's visible defs. The runtime table is
      the hard boundary; the static gate gives precise refusals and
      catches capability-carrying calls the name filter would only
      stop deeper in.
    - READER'S BRANCH ENV. Eval runs in a CHILD of the session env:
      real bindings resolve through the parent chain (thunks force
      through their own captured closures), and nothing the example
      does can leak into the session env.
    - CAPS. Fresh step budget per call (Eval.make_budget, default
      limit) -- the lisp/ recursion/loop guardrail; plus a wall-clock
      cap checked between top-level forms. Blocking prims (sleep,
      http-get, llm/agent families) are not whitelisted, so nothing
      inside the example can park the fiber past the step budget. A
      runaway example's budget exhaustion converts to [Refused], NOT
      a bare Budget_exceeded: the only budget in play here is the
      nested one (the caller's is restored in [finally]), and guard --
      the only catch Nopales has -- deliberately re-raises
      Budget_exceeded, so (book/verify) must see a refusal to render
      the runaway as a hole instead of dying with the report.

    The caller's current_budget and the ambient rim are saved/restored
    around the nested run (Control.run_with_rim nests by design; same
    pattern as Session.bench). *)

open Pricklypear_lisp.Ast

exception Refused of string
(** Static gate refusal. The reason names the offending form or
    capability; callers render it as a drift-hole-style error box. *)

(* POST /api/prim (borge/remote-eval.borg server-endpoint).

   One prim call per request, dispatched through the session prim table
   (the SAME table /api/eval dispatches through -- the one
   [register_session_prims] + control/CRUD registrations build) so
   identity/author/branch are exactly as an in-process eval. Body:
   {name: str, args: [json?]}. Args deserialize via the shared codec
   (Prims_pure.json_to_value), the result serializes via
   Prims_pure.value_to_json, and failures use the shared
   Prims_pure.error_to_json -- so a remote client observes identical
   values and exceptions to an in-process eval.

   GRANULARITY: per-DB-hit, not per-expression (see placement in the
   spec for the mitigation). Same auth path as /api/eval (basic-auth /
   cookie session). No new privilege -- a prim call is equivalent
   privilege to an eval that performs the prim.

   REFUSE-OR-FORWARD: prims that MUST execute server-side to mean
   anything (route/fork/merge/checkout/auth-admin) are refused with a
   structured {ok:false, kind:"server_only", name, reason} error citing
   locality rather than pretending to proxy them. Classification is
   DERIVED from prim-registry metadata (Primitives.is_server_only -- set
   where the prim was registered), never a hand-maintained list. *)

```
(* Pricklypear Image -- /tree browser face over the one tree
   (one-tree.tree-browser).

   Generic store-tree navigation on the session lens: breadcrumb from
   tree/ancestors, ONE level per render (CHILDREN-BY-LEVEL, never a
   subtree walk for a page), lazy expansion through htmx partials
   (/partials/tree -- one children query per expand), ranked order from
   sibling-order, kind filter, as-of-gen view (?gen=) with head-diff
   highlighting, and a node detail pane (body JSON, created/updated,
   author, rank, out-links/backlinks, edit affordance gated on
   tree/upsert auth rules).

   Complements /data (typed-row tables), /bindings (code), /sys (admin
   store-tree). The existing tree/* (scripture docs) package is
   untouched in v1. Confinement per tree-read-prims: an identity lists
   only its own garden/data prefixes + data.shared + its branch chain's
   store-tree root; private paths are not listable. *)

```
(** Pricklypear Image -- Network primitives (single-image.net-prims).

    v1: EGRESS ONLY. (tcp-connect host port) opens an outbound TCP
    connection via the OCaml Unix module (synchronous); stream-read/
    write/close operate on an opaque handle stored in the session's
    [net_streams] table.

    Ingress (tcp-listen, spawn-service) and the Eio.Net-native path are
    deferred to v2 (BORGE-1785967056, BORGE-1785968883 -- Eio switches
    are run-scoped, no standalone make, so persistent handles need a
    service-manager switch wired from boot). v1 uses Unix blocking
    sockets, matching how do_http_get shells out synchronously.

    Capability: anonymous sessions denied; quota on open streams
    (default 16) prevents resource exhaustion. *)

(** Classify an exception as an *expected* runtime/user error that
    should be logged but NOT filed as a reliability incident.

    Route-handler eval can raise deterministic [Interp_error] variants
    that are the user's fault (bad input, wrong arity, runaway step
    budget), not a reliability fault in the image. These still get
    emitted to the ops log (stderr + ring) so they're observable, but
    [record_event] is skipped so they don't spawn a TODO/incident row
    for every user mistake.

    Genuine faults -- [Not_a_function], [Prim_error], [Unbound_var],
    [Parse_error] (a seeded route shouldn't fail to parse at runtime),
    and any non-[Interp_error] exception -- are still filed. *)

  (* sync/push -- apply a client push for the caller's data subtree
     (borge/local-first.borg sync, v1 two-way + three-way / data-only).
     Takes the client (path, hash) manifest (same shape as sync/plan)
     plus a list of (path, envelope-json) pairs for the bodies the
     client holds, and an OPTIONAL third argument: the base manifest
     the client recorded at its last successful sync (the common
     ancestor -- the __base.json the client pins from the previous
     round's merged_manifest). The server classifies its own
     data.u.<user>.* manifest against the client's, then:

       - ClientOnly paths (server missing the node) are applied through
         the typed-boundary-validated datum write surface
         (Sync.apply_client_node).
       - Diverge/conflict paths (both sides hold different hashes) are
         LWW-ARBITRATED per sync-conflicts v0: the client envelope wins iff
         its updated_at (epoch, stamped by the lens substrate on every
         local put) is STRICTLY newer than the server node's; otherwise
         the server copy stays. EVERY resolution is surfaced with its
         winner (lww_client_won / lww_server_kept) -- the obituary rule
         applies to the losing side; nothing is silently dropped.
       - With a base, the FULL three-way plan (Sync.plan_of) runs:
         clean client edits apply (theirs_add/theirs_mod), client
```

```
         DELETIONS propagate (theirs_del), server deletions come back
         as client_delete_paths for the client to mirror locally, and
         conflicts get the same LWW arbitration.
       - ServerOnly paths are returned so the client can pull them.

    Returns a JSON object:
      {mode, applied, client_only, server_only, diverge,
       server_only_paths, diverge_paths, conflicts, lww_client_won,
       lww_server_kept, client_delete_paths, merged_manifest,
       generation}
    where merged_manifest is the server's post-apply subtree manifest --
    the (path, hash) list the client records as its NEXT round's base --
    and generation is the new (branch, generation) coordinate to pin.
    Code-lens sync (the b.<lens> code paths) is NOT in scope here - it
    is the branch-pointer move (promote/merge), a separate path; callers
    filter the manifest to data paths first.
      (sync/push client-manifest client-bodies [base-manifest])

98 image/lib/prims_hyper.ml

```
(** Pricklypear Image -- hypermedia harness shim.

    The soup/ tree prims + the host-agnostic helpers (assoc_of,
    render_handler_value) were lifted into the shared pure-prims layer
    [pure/prims_soup.ml] so both the image and the agent register the
    SAME tree prims (spec: hypermedia-harness.kernel-prims SHARED
    KERNEL). This file re-exports them so image call sites
    (Prims_hyper.register_pure_prims / assoc_of / render_handler_value)
    stay unchanged.

    The session-capturing prim route/dispatch stays registered INLINE in
    session.ml (register_hyper_route_dispatch, right after this module's
    register_pure_prims call) so it can close over Session.t without a
    dependency cycle -- mirrors register_crud_prims / register_net_prims. *)
