651  (* Private prim used by the with-step special form in eval.ml. NOT
652     USER-VISIBLE: routed to under name __step__ by eval.ml, never
653     `(with-step "name" (lambda ...))` from a plain prim call.
654
655     (__step__ "name" <lambda>) is a checkpoint boundary (borge/jobs.borg
656     step-checkpoints):
657       - Outside a job (Jobs.current_job_id_opt () = None, e.g. an HTTP
658         request or REPL) it is a PLAIN thunk call -- no checkpoint.
659       - Inside a job (the runner binds the job id around eval), the
660         thunk's result is memoized under (job_id, name): first execution
661         runs the thunk and writes a job_steps row; re-execution (a retry)
662         returns the stored value WITHOUT re-running the thunk.
663
664     Exactly-once with (with-transaction (step ?)): the checkpoint INSERT
665     rides Store.current_conn -- when the caller is inside
666     with_transaction, the insert lands in the SAME transaction as the
667     thunk's writes, so it commits or rolls back atomically with them (a
668     failed/later-raised step leaves no checkpoint; a retry re-runs). If
669     the THUNK ITSELF raises, no checkpoint is written (the exception
670     propagates, rolling back the surrounding transaction if any). *)

  (* (with-public-write (lambda () body...)) -- run body with write privilege
     so public route handlers can create data_rows / notes captures.
     Elevates anonymous only (logged-in sessions already write). Restores
     identity afterward. Prefer for narrow public forms (signup), not general
     unauth APIs.

     Elevates BOTH the live session manifest AND the per-request context
     manifest. CRUD prims (create/deftype) read their anon guard from
     Request_context.manifest (the gate-time snapshot, per BORGE-1784434193
     cotenant fix); without elevating the snapshot, the guard sees the stale
     "anonymous" and silently denies (create returns a VStr, seq discards it,
     the handler renders its thanks page with no row written). *)

  (* Product shell: nav HTML + theme CSS (image.product-theme).
     image.http-robustness invariant 3: this runs on every request, so
     a FAILED shell eval must not re-attempt + re-warn per request
     (ui_shell_retry_at suppresses for shell_retry_secs after a throw;
     reset on checkout / success). Emergency chrome fallback is
     unchanged: when ui_nav_html is None, http serves emergency nav.

     image.product-theme: invalidation is DEPENDENCY-TRACKED, not
     TTL-based. A successful shell eval records the binding names it
     read (ui_shell_reads, via Env.lookup_hook, armed only around these
     two evals). A define of a name in that set busts the cache (see
     touches_shell); anything else leaves it. The cache is therefore
     fresh until a real dependency changes -- no 60s window serving
     stale CSS, no prefix-guess busting on unrelated defines. Checkout
     and load-library still bust unconditionally. *)

106 image/lib/session_registry.ml

```
(** Pricklypear Image -- per-identity session registry
    (image.per-identity-sessions).

    One [Session.t] per attached identity instead of one shared
    session that every request flips to its own branch:

    - the anonymous session serves all unauthenticated traffic, parked
      on system/main;
    - each authenticated username gets its own session, built lazily
      on first attach, parked on that identity's branch (personal for
      humans, <parent>/agent for agents), with its OWN Store.t (own
      pgx connection -- checkout never moves another identity's branch);
    - attach = select (or create) + a cheap staleness stamp check.
      Attach never hydrates an unchanged session
      (image.boot-request-cost) and never mutates another identity's
      session.

    Sessions are never expired in v1 (user count is small; revisit
    with an LRU if public signup appears). *)

(* Load persisted function_defs + routes into the env.
   Returns when finished (caller may then seed libs/ which overwrite).

   Load order is critical: many personal pins are *values* evaluated at
   define-time (e.g. ui/menu = (list (menu/link ?))), not lambdas.
   Those bodies need parent helpers (menu/link, menu/group, ?) already
   bound. Store.list_function_names returns effective defs only (closest
   branch wins) but does NOT topological-order dependencies across the
   parent chain. We therefore load the full chain parents-first
   (depth DESC) and redefine so child overrides win last.

   Historical bug: depth ASC + first-wins loaded personal ui/menu BEFORE
   system menu/link ? define failed ? ui/menu unbound ? (ui/nav) fails ?
   silent fallback to OCaml default_nav_nodes ("navbar disappeared"). *)

(** Child own names left-joined to parent: name, child_updated,
    parent_updated opt. *)
(* ---- branch status (branching.branch-status) ----

   Git-style per-name status of a branch against its parent chain, as ONE
   derived read of the tree-time substrate (tree_versions, migrations
   018-021) keyed on the base_gen merge-base coordinate (migration 024).
   Hash-first per tree-time: equal hash = prune; bodies are never fetched.

   Per name (fn | type | route), with values resolved closest-ancestor-wins
   (a tombstone or missing newest version on one branch means that branch
   is dead for the name and the walk continues up, matching the
```

```
   scaffolding/unbind semantics):
     b = branch value at own head
     p = parent-chain value at parent head
     a = parent-chain value at base_gen (the fork-time base)
     own = a live scaffolding row exists on the branch (the pin)

   HASH DOMAIN (make-phase lesson, 2026-08-28): the STORED
   tree_versions.hash column is NOT comparable across write paths --
   tree-first writes (Tree_store.hash_body over compact OCaml JSON) and
   mirror writes (009 trigger digest over PG jsonb::text, which spaces
   after colons) produce DIFFERENT digests for identical bodies (020
   itself calls the stored hash "a consistency artifact, not content").
   Comparing stored hashes mislabeled identical pins as diverged. Status
   therefore computes digest((body->'body')::text) AT QUERY TIME -- one
   canonical domain (PG jsonb::text) regardless of which path wrote the
   row. The stored column stays for retention/GC bookkeeping and
   same-path gen-diff; a global rehash is tree-time's scope, not ours.

   Tombstones are the reserved 019/020 marker (body->_tombstone). Deletion
   on a branch REVEALS the parent binding (unbind semantics), so there is
   no "locally deleted" status -- a delete is a pin removal, not a divergent
   state.

   APPROXIMATION (documented in the spec): base_gen bounds ONLY the direct
   parent's versions; ancestors above the parent contribute their full
   head. Exact for the dominant topology (empty child of system/main);
   for deeper chains, post-fork writes on grandparents fold into the base.
   Accepted v1; revisit with per-ancestor bounds if it ever misleads. *)

(* ---- type_defs ----

   Per spec [storage.types]: user declares a type with (deftype 'name
```

```
   field1 field2 ...). The declaration is INSERTed into type_defs with
   branch_id = current branch and fields = JSON array of strings (the
   field names, in declared order).

   The data DOESN'T live in a per-type table: packed in migration 003's
   note that generating one PG table per Lisp type would require
   runtime DDL breaking additive-migrations-only. Instead, all data
   rows are stored in the shared data_rows(type_name, fields jsonb)
   table, and type_defs is pure declaration metadata. (Type
   declarations MAY eventually guide field-level validation; for now
   they're documentation.)

   The recursive-CTE override walk applies to type_defs the same as
   function_defs / view_bindings: ancestors' types are visible, child's
   definition wins on name conflict. *)

(* Merge a source branch's function_defs into a target branch.

   Per spec [branching.merge]:
     (merge 'alice/experiment 'alice/main)
   -> copy all function_defs from source to target (upsert).
   Policy: admin-only merges to main; per-user can merge into their
```

```
   own branches. Policy is enforced at the Lisp intercept layer
   (session.ml); Store.merge_branch just does the SQL.

   branching.branch-status S3: status-driven merge. Into the source's
   PARENT: upsert ONLY names the source moved since base_gen (ahead-new /
   ahead / diverged); behind names would clobber the parent's newer work
   and are skipped; synced/clean names are already identical. Conflict
   report = the diverged set (both sides moved since the fork base) --
   genuine conflict detection; resolution stays LWW (report-only).
   Any other target (no shared base): head-vs-head fallback -- upsert
   source fns whose body differs from the target's own row, no report.
   TODO: schema-merge for type_defs -- only main accepts schema changes
   via special migration-governed merge.

   Wrapped in a SERIALIZABLE transaction via [with_transaction] since
   it16 (previously best-effort atomic -- carried-forward since it9). *)

(* ---- code-history over tree_versions (tree-time.projections, Phase 3) ----
   Re-implements branching.code-history / code-diff over the versioned tree
   (tree_versions) instead of the 012 before-image table, KEEPING SIGNATURES
   UNCHANGED.

   SEMANTIC NOTE (recorded in tree-time.coexistence-plan Phase 3): 012 stored
   the OLD before-image per UPDATE/DELETE (never on the first INSERT);
   tree_versions stores the post-write head payload at each gen. A tree-backed
   history read therefore reports ONLY the rows STRICTLY BELOW HEAD -- the
   previous states, newest-first -- which the projections doc phrases as "read
   the version row at gen-1". The current head row (the live state) is never
   history, so an insert-only fn has no history until it is rewritten or
   deleted, exactly like the 012 table. Delete-then-recreate leaves a
   middle TOMBSTONE row (op=DELETE) below head, which is preserved.

   FALLBACK: when the code path has NO version rows yet (a pre-019 write --
   the 019 shadow only captures writes after installation), fall back to the
   012 table so no pre-shadow historical depth is lost during the coexistence
   window. Post-shadow history is complete in tree_versions. *)

(* The inner definition payload of a code version row. The tree payload for a
   fn/type/route node carries the code under a 'body' key (fn: {body, params};
   type: the fields list; route: the handler JSON) -- the same shape 012 stored
   in function_defs.body / type_defs.fields / view_bindings handler. *)
let code_body_of_version (v : Tree_store.version) : string option =

        candidates

(* Tree-backed code history for [name] on [branch_id], newest-first.
   Only rows STRICTLY BELOW HEAD are history -- the 012 table captured
   before-images on UPDATE/DELETE only (never on the first INSERT), and the
   projections doc defines a history read as "the version row at gen-1".
   So the current head row (the live state) is EXCLUDED; the newest history
   entry is the state just before the latest change. Empty when the name has
   no code path OR only a first-insert head row (no superseded state yet) --
   caller falls back to the 012 table so pre-shadow depth is never lost. *)

(** (code-restore name [n] [owner/branch]) -- restore a code node (fn/type/
    route) at head-n as a NEW write at head+1 (restore-by-write). This is
     the
    code-path analogue of (undo) (which is datum-path only): gen-read +
     write
    the same value back through the code write surface (upsert_fn /
    upsert_type / upsert_route), so the reverse mirror re-populates
    function_defs / type_defs / view_bindings and the restore itself is
```

```
    versioned + redoable (the restored value becomes the new head; calling it
    again restores the state before that). The below-head semantic matches
    code-history's "read the version row at gen-1": n=1 restores the state
    just before the latest change; n=2 the state before that. Out-of-range n,
    no history, no body, or an unsupported rel are clean error strings (never
    a crash). Consumers: tree-time.consumers -- code-restore = gen-read +
    define, the lossless-redefine pattern the 012 design documented by hand,
    now a real prim. [author] is the session user, the fallback only when the
    source version row carries no author. *)

(* ---- tree-time.gc (5.3): retention worker ------------------------------
   Retention is habitat data + the jobs runner, composed on the existing
   gen-window partitions:
     - policy rows (tree_retention_policy, migration 022) declare per-path-
       class retention (code keeps all; data per-type, default
    keep-everything
       until a policy exists).
     - tree_versions_retain(path_class, keep_windows) (SQL, 022) computes
    the
       retention floor from the live head gen, ROLLS UP the surviving state
    of
       fully-retired paths to CHECKPOINT rows at the floor boundary (so
    as-of
       reads of ancient gens still resolve), then DROP PARTITIONs every lazy
       gen-window entirely below the floor (never the base window).
    Idempotent
       + conservative; on the real habitat it is gated by a scheduled job on
       the jobs runner (migration 015), not ad-hoc deletion.
   The first long pole is code paths (tiny); retention is a TODO until a
   path class outgrows its welcome -- measured via /timing-style storage
   accounting, not vibes. *)

110 image/lib/sync.ml

```
(** image/lib/sync.ml -- borge/local-first.borg sync (campaign 8.3).

    The SERVER-SIDE sync merge authority. Sync = three-way tree-diff
    (branching.borg / one-tree.branching-interaction), keyed on subtree
    node hashes (the git protocol in miniature):

       1. Client sends its (path, hash) manifest for the lens subtree.
       2. Server compares against its own subtree hashes; reports which
          paths differ or are missing on each side.
       3. Each side sends the node BODIES the other is missing or has
          stale.
       4. Server applies the three-way merge (common ancestor = the
          last-synced generation) and returns the merged subtree state.

    The envelope hash is the negotiation; the file is the transfer. On
    the tree_nodes side the hash is [Tree_store.hash_body] (sha256 over
    the canonical body), the SAME content hash the client's lens
    substrate computes offline ([Lens_store.content_hash]) -- one hash
    scheme, both sides, so a Same/Diverge classification is meaningful
    across the wire.

    This module owns the pure reconciliation + three-way merge planner
    (the heart of the exchange -- classification of a manifest union and
    the conflict-free / LWW-v0 plan), plus the server-side harness:
    reading its own subtree manifest from tree_nodes and applying a
    validated reconcile plan back to the store.

    The client-facing transport/exchange (an HTTP rendezvous that ships
    the manifest + bodies) is owned by the client lens / sync client;
    this module is the server half: given a client's (path, hash)
    manifest for the current lens, it decides what the server must send
    (ServerOnly = pull), what the client must send (ClientOnly = push),
    and where the three-way merge (base = last-synced) conflicts.
*)

(** Apply a whole reconcile/merge plan to the server: for every actionable
    row the plan directs the server to take (Theirs_add / Theirs_mod /
    Theirs_del are applied from the client bodies; a Conflict is LWW-
    arbitrated per sync-conflicts v0 -- client envelope strictly newer wins
    and is applied, otherwise the server copy stays), look up the client
    node envelope. Since this server harness applies the PLAN (not the
    bodies it must first receive), the client bodies are passed as an
    assoc path -> envelope JSON. Every resolution is SURFACED: the report
    lists the conflicts with their hashes, which side LWW picked per
    path, and the Ours_del paths the client must mirror-delete locally. *)

(* ---- sync-conflicts v0: LWW-per-node resolution (applied + surfaced) ----

    Detection was 8.3 (hashes classify; conflicts REPORT-only). The v0
    RESOLUTION policy sync-conflicts names is LAST-WRITER-WINS per node,
    updated_at arbitrating, with every loss SURFACED (the obituary rule
```

```
353     applies to sync losses -- no silent drop). One clock, both sides:
354     the client lens substrate stamps its envelope updated_at as an epoch
355     float (string_of_float Unix.gettimeofday); the server reads its node
356     updated_at as the same epoch float (extract(epoch from updated_at)).
357     The client wins a diverge/conflict pair iff its stamp is STRICTLY
358     newer -- ties and missing/unparseable stamps keep the server copy
359     (deterministic, conservative; a materialized-from-server envelope
360     carries the server's PG-format stamp, which is intentionally not
361     parseable as an epoch here, so an unedited pull can never wrongly
362     out-vote a newer server edit). Cross-machine clock skew is the
363     classic LWW tax; the spec accepts it for v0 and surfaces every
364     resolution. `commit` and the sync/push prim both apply this policy. *)
365
366 (** The server's updated_at epochs (float seconds since the epoch) for

112 image/lib/tree_store.ml

```
(** Pricklypear Image -- ONE TREE store (spec [one-tree]).

    The tree is the substrate that will replace the relational
    scaffolding (function_defs / type_defs / view_bindings / data_rows)
    behind the UNCHANGED Nopales prim ABI. This module owns:

      - the PATH GRAMMAR (ltree labels, dots not slashes),
      - the reversible label codec that MUST match migrations/009_tree.sql
        [tree_enc_label] / [tree_uuid_label] exactly,
      - the node ENVELOPE (jsonb) constructors/parsers,
      - content hashing (sha256 over the canonical body).

    P1: pure helpers + DB read/verify helpers. No behavior change yet --
    the tree is written by the SQL shadow-mirror triggers (migration 009)
    and read here for validation. P3 flips prim/store reads to this
    module; P4 makes the tree the write-truth.

    Branch inheritance is NOT baked into the path. The override-walk is
    realized by trying a name under each branch prefix from self up the
    parent chain (first hit wins). Datum paths are USER-OWNED (not branch
    lenses): data.u.<user>.<type>.<id> + data.shared.<type>.<id> per
    [one-tree.branching-interaction] /data DECISION. *)

(** Branch status (branching.branch-status): git-style
    clean/ahead-new/ahead/behind/diverged/synced classification over the
    tree-time substrate (tree_versions) keyed on base_gen.
    Needs Postgres (scripts/dev.sh). Skips if unreachable.

    Verifies: fork records base_gen = parent head gen; empty fork reads
    clean; own new fn reads ahead-new; post-promote pin reads synced;
    parent-only move reads behind; both-sides move reads diverged; merge
    upserts only ahead/diverged and ADVANCES base_gen (post-merge the
    branch reads synced, not diverged); status agrees with diff_branches
    head-vs-head on the diverged fixture. *)

120 image/test/code_history_tree_test.ml

```
(** tree-time.projections Phase 3: branching.code-history / code-diff now read
    from the versioned tree (tree_versions) instead of the 012 before-image
    table, keeping signatures UNCHANGED.

    SEMANTIC NOTE (tree-time.coexistence-plan Phase 3): 012 stored the OLD
    before-image per UPDATE/DELETE (never on the first INSERT). tree_versions
    stores the post-write head payload at each gen, so a tree-backed history
    read reports ONLY the rows STRICTLY BELOW HEAD -- the previous states,
    newest-first "read the version row at gen-1" -- and the live head row is
    never history (an insert-only fn has no history until rewritten/deleted).
    The 012 table remains the fallback source only for pre-shadow (pre-019)
    names, so no historical depth is lost during the coexistence window.

    These tests exercise the tree-backed path directly (Store.list_code_history
    routes to tree_versions when the code path has version rows) and confirm
    code-diff still produces a diff against the nth-newest history entry.

    Needs Postgres (scripts/dev.sh). Skips cleanly when unreachable.

121 image/test/code_restore_test.ml

```
(** tree-time.consumers: code-restore -- the code-path analogue of (undo)
    (which is datum-path only). Reads the versioned state at head-n and
    re-writes it back through the code write surface (upsert_fn / upsert_type
    / upsert_route), so the reverse mirror re-populates function_defs / type_defs / view_bindings and the restore itself is versioned + redoable.
    "code-restore = gen-read + define" (the 012 lossless-redefine pattern).

    Below-head semantic matches code-history's "read the version row at gen-1": n=1 restores the state just BEFORE the latest change; an insert-only code node (nothing below head) has no state to restore.

    These tests exercise Store.code_restore directly. Needs Postgres (scripts/dev.sh); skips cleanly when unreachable.

(* Pricklypear Image -- example-eval restriction tests (no DB).

   habitat-book.eval-examples: (example-eval src) parses + evals
   Nopales source in a RESTRICTED environment. These tests pin the
   restriction surface against a synthetic prim table + env built the
   same way primitives_test builds them (no Session/PG):

     - whitelist surface: pure + read-only DB + supplement present;
       mutation families and escape hatches ABSENT (spec verify
       smoke: "define/route/create prims are absent from the example
       table");
     - static gate: mutation special forms refused, quoted data inert,
       capability-carrying calls refused via known_fn;
     - runtime boundary: prims absent from the restricted table fail
       closed -- including through macro expansion and function bodies;
     - env semantics: parent bindings resolve, thunks force, nothing
       leaks back (child env);
     - caps: step budget kills runaway nesting -- CONVERTED to Refused
       (budget -> refusal) so (book/verify)'s guard can hole it.

   The eval path runs under Example_eval's own nested rim, so no outer
   Control_rim is needed in the test (bench precedent). *)

129 image/test/jobs_test.ml

```
(** Durable background jobs -- node-shapes + runner (borge/jobs.borg).

    DB-backed regression tests for the dedicated `jobs` table
    (migrations/015_jobs.sql) and image/lib/jobs.ml. Needs Postgres
    (scripts/dev.sh); skips cleanly/unreachable.

    Covers the job node-shapes + runner verify stanzas:
      - job node create / claim / status transitions with runner-owned
        field confinement (submitted_by + branch pinned at submit; the
        visibility prims confine to the caller unless admin).
      - claim SKIP LOCKED skips a row locked by a concurrent connection.
      - exponential backoff schedule (failed retry is re-queued into the
        future; exhausted attempts => dead).
      - dead-runner reaper fails stale 'running' rows left by a dead
        runner_id (retry under attempts/backoff or dead at exhaustion).
      - cancel of a pending job (and only pending; not-yours rejected).

    The boot-time runner fiber (boot.ml) is thin glue over these Jobs
    functions (claim -> eval -> record); the substantive node-shapes and
    runner behaviors live in Jobs and are asserted here directly.

130 image/test/local_first_prims_test.ml

```
(** local-first prim tests (borge/local-first.borg lens-model +
    replication-units, campaign 8.1).

    Needs Postgres (scripts/dev.sh). Skips cleanly when unreachable.

    - lens/fork names + creates a lens branch as a NAMED CHILD of the
      checked-out branch (the pinned <owner>/lens-<device>[-<date>]
      contract); the fork is an EMPTY-LENS child (parent pointer only,
      copy-on-fork) so it owns zero code rows and resolves through
      branch ancestry. The server branch stays the parent; single-writer
      per lens is preserved by construction (no server writes into it).
    - replication/unit materializes the exact authorized-read subtree the
      identity would replicate: data.u.<user>.* + data.shared.* + the
      code lens + branch ancestry; path-prefix RLS confinement is the
      replication boundary.

```
(** Pricklypear Image -- hypermedia harness kernel prims tests (no DB, no
    session).

    Tests the PURE soup/* lambdasoup bindings by evaluating Nopales forms
    against a prim_table with register_pure_prims. Mirrors primitives_test's
    pattern: build the table directly, eval via eval_string_direct.

    Spec: borge/hypermedia-harness.borg (kernel-prims verify stanza).
    No route/dispatch here (that needs a session -- verified via pp_eval +
    the fidelity smoke). *)

```
(** tree-time reads-as-of-gen prim surface tests
    (tree-time.reads-as-of-gen).

    Exercises the USER-FACING gen coordinate built on the versioned read
    foundation (versioned_head/versioned_history + the `version` row type,
    landed in the 5.1 close-out):

      - tree/get <path> <gen>  : optional :gen N resolves the node at that
        gen (versioned), omitted = head (live tree_nodes).
      - gen-read <path> <gen>  : node body at gen as version JSON; supports
        absolute b.*/data.* paths AND relative logical suffixes crossed
        through the branch lens chain (closest-wins).
      - gen-diff <path> ga gb  : node-granular diff -- hashes first, walk on
        mismatch; returns "same" when both leaves hash-identical.
      - undo <path> [n]        : restore the value at head-n as a NEW write
    at
        head+1 (restore-by-write) for datum paths; the restore is itself a
        versioned append, so undo is lossless + redoable.

    Needs Postgres (scripts/dev.sh). Skips cleanly when unreachable.

138 image/test/sync_db_test.ml

```
(** image/test/sync_db_test.ml -- borge/local-first.borg sync (campaign 8.3),
    DB-BACKED half of the sync merge authority (image/lib/sync.ml).

    The PURE core (classify / plan_of / actionable / JSON) is covered by
    sync_test.ml (pure, no PG). This file exercises the DB-backed harness
    the server-side commit path uses:

      - server_manifest reads the server's subtree (path, hash) manifest
        straight from tree_nodes (the exchange's server-side offer).
      - commit applies a client push (theirs_add) node through the
        typed-boundary-validated datum write path, and SURFACES conflicts
        report-only (sync-conflicts v0: LWW keeps server, conflict reported,
        no silent loss).

    Needs scripts/dev.sh Postgres; skips cleanly when unreachable.
*)

```
(** local-first sync authority tests (local-first.sync, campaign 8.3).

    The heart of sync is PURE (no Postgres): manifest classification
    (the exchange's conflict DETECTION at node granularity) and the
    three-way merge planner (base = last-synced, ours = server,
    theirs = client -- the campaign-3 diff philosophy). These tests
    exercise the pure core exhaustively, plus the JSON report rendering
    the sync/plan prim returns. The DB-backed harness
    (Sync.server_manifest / Sync.apply_client_node / Sync.commit) is
    exercised against the live dev image / shared PG when reachable, and
    skipped cleanly otherwise.

    Each test uses synthetic hashes (h1..hn) -- content identity is
    opaque to the planner; only equality/membership matters.

```
(** Tree datum prims regression tests (one-tree.tree-datum-prims).

    The tree prim family must operate on DATUM nodes directly -- not only on
    hierarchical kinds. tree/upsert with kind="datum" is the path-explicit
    variant of create/update: caller-supplied (or placeholder-generated)
    path, same typed-boundary validation, ON CONFLICT upsert, and the
    tree_data_rows view stays in sync so (get 't id) / (rows 't) reflect the
    node identically to one written via create. tree/move re-homes a datum
    (rewrites path + payload.path); tree/delete removes it; the readers
    (tree/get, tree/list, tree/list-kind) are kind-agnostic so they return
    datum nodes too. created_at is stable across an upsert rewrite while
    updated_at advances.

    Needs Postgres (scripts/dev.sh). Skips cleanly when unreachable.

    Acceptance (one-tree.tree-datum-prims verify stanzas):
      - tree/upsert a datum node of a declared type (all required fields) ?
        node at the given path; (get 't id) sees the same fields.
      - tree/upsert a datum missing a required field ? clean rejection
        naming the field (identical to create).
      - tree/upsert an existing datum path with a changed field ? body
        updates in place; the projection reflects the new value.
      - tree/move a datum node to a new path ? (get 't id) at the new path
        returns it; old path is gone.
      - tree/delete a datum path ? node removed.
      - tree/get / tree/list / tree/list-kind return datum nodes.
      - tree/get of any node returns JSON with created_at and updated_at;
        created_at stable across an upsert rewrite, updated_at advances.

```
(** Tree-edges tests (one-tree.tree-edges).

    An edge IS a node: kind=link at <source-path>.lnk.<uuid>, body
    {to, kind, label?}. "from" is positional (never in the body); to is
    stored verbatim as branch-qualified path text and MAY dangle;
    resolution is a read-time act against the reader's lens. Edges
    inherit the whole tree stack: versioning (gen-read/gen-diff/undo),
    authorship, branch ownership, lens visibility. tree/delete and
    tree/move report incoming-edge counts (warn, not forbid).

    Needs Postgres (scripts/dev.sh). Skips cleanly when unreachable.

    Acceptance (one-tree.tree-edges verify stanzas, minus the :ref
    materialization stanza -- that half is deferred with the typed-
    boundary :ref work; see BORGE issue on the tree-edges subsection):
      - link a?b: (out-links a) lists b resolved; (backlinks <b-path>)
        includes the edge path.
      - tree/move of the target: the edge reports dangling on read;
        textual backlink still finds it (legacy half).
      - tree/delete of a node with 2 inbound edges reports count 2 and
        succeeds (warn, not forbid).
      - edge nodes are versioned: gen-diff shows edge add; undo of
        unlink restores the edge.

```
(** Lens-aware tree read prim tests (one-tree.tree-read-prims,
    tree-store + crud + prims_db lens functions, BORGE-1785516993).

    Needs Postgres (scripts/dev.sh). Skips cleanly when unreachable.

    Acceptance (issue 1785516993):
      - a relative logical path (fn/type/route/pkg suffix) resolves across
        the session's branch chain with closest-ancestor-wins (same as
        function_defs): a child override shadows the parent, and an
        effective definition from system/main is visible on a child.
      - tree/lens-get returns exactly one node (the effective one);
        tree/lens-children/subtree read under the effective branch.

```
(** tree-time.gc (5.3): retention worker surfaces.

    Exercises the retention-policy-as-habitat-data Store functions
    (retention_set_policy / retention_delete_policy / retention_list_policies)
    and the retention worker entry point (retention_run) in their two safe,
    NON-DESTRUCTIVE deterministic forms:

      (a) NO whole-class policy  -> retention keeps everything: retention_run
          returns [] (the worker is never invoked / no-op keep-all gate).
      (b) whole-class policy with keep_windows large enough that the retention
          floor CLAMPS to the base-window boundary (gen 1000) -> the worker's
          early-exit path returns (0,0): nothing beyond the base window is
          retentive yet, so nothing is checkpointed or dropped.

    The DESTRUCTIVE rollup + DROP PARTITION path (checkpoint-then-drop of
    lazy windows entirely below a non-trivial floor) is verified by the
    migration's own function tree_versions_retain against an isolated scratch
    DB (see the 5.3 notes log), NOT here -- against the shared dev PG that
    would drop real partitions. These tests keep the policy rows scoped to a
    throwaway type and delete them after.

    Needs Postgres (scripts/dev.sh); skips cleanly when unreachable.
*)

145 image/test/tree_sibling_order_test.ml

```
(** Sibling-order tests (one-tree.sibling-order).

    Children get a user-controlled order via the nullable rank column
    (migration 025): canonical base-36 fractional strings compared as raw
    bytes, midpoint allocation, rebalance on exhaustion. Reads order
    rank COLLATE "C" NULLS LAST, path ASC; reorder is an ordinary
    versioned write (gen-read/undo carry order); a lens override of a
    node owns its own rank.

    Needs Postgres (scripts/dev.sh). Skips cleanly when unreachable.

    Acceptance (one-tree.sibling-order verify stanzas):
      - insert three children, move third before first: children-of
        returns the new order.
      - unranked siblings sort after ranked, path-ordered among
        themselves.
      - reorder is versioned: gen-read at old gen shows old order; undo
        restores.
      - a lens override of a node owns its rank; the parent's rank is
        unchanged.

```
(** tree-time Phase 1 dual-write shadow tests (tree-time.versioned-leaves).

    Every tree_nodes write is shadowed into tree_versions by the
    AFTER-trigger (migration 019 tree_version_append_trg). These tests
    exercise that shadow through the real store write paths and the
    versioned read surface added to Tree_store (versioned_head /
    versioned_history), then clean up after themselves:

      - datum create -> one version row; body/hash equal the live node;
        versioned_head (with no at_gen) == live tree_nodes head.
      - datum update -> the SAME (path, gen) chain grows (append); gen
        strictly increases; versioned_head returns the newest (the body
        that is live), and versioned_head ~at_gen:oldest returns the
        original body (an as-of-gen read).
      - datum delete -> a TOMBSTONE version row is appended at a higher
        gen (a row, never a DELETE); versioned_head reports the tombstone.
      - code-path fn write -> a version row under the b.<branch>.fn.*
        path with the branch's branch_generations bumped (not the data
        tree_generations counter).

    Needs Postgres (scripts/dev.sh). Skips cleanly when unreachable.
*)

(define ai/copilot-seed
  "You are the co-pilot for a running Pricklypear IMAGE (a multi-user Lisp
     OS), NOT the cactus genus Opuntia/Pricklypear plant.\n\nPricklypear is
     software: users have live images; Lisp functions are durable data in
     Postgres; branches version code; routes bind functions to HTTP; the UI
     is htmx. Kernel prims include list-bindings, get, rows, create,
     update, define, route, render-html, agent-session-new, agent-say,
     propose-function, install-function.\n\nRules:\n- Prefer facts from the
     prompt CONTEXT block (user, branch, bindings, etc.).\n- If CONTEXT
     does not contain the answer, say you do not know from this image -- do
     not invent store contents or pretend to be a botany article.\n- Answer
     clearly and briefly unless asked for detail.\n- Never describe
     Pricklypear as a cactus unless the user is clearly asking about the
     plant in nature (then you may clarify the name collision).\n- When
     tools are available, use them to inspect the live image rather than
     guessing.\n- After (load-library \"notes\"), the note slug agents is
     this habitat's living AGENTS.md. Read it with (notes/doc/get
     \"agents\"). Update it with notes/doc/upsert when durable agent
     guidance should change.\n- Knowledge wiki: (wiki/ingest-from-source
     ?), (wiki/query ?), (wiki/lint); links are [[slug]] in outline
     bodies.")

155 libs/book/lib.pp

```
;; package book -- the spec IS the book: borg chapters as live habitat pages.
;;
;; Spec: borge/habitat-book.borg (habitat-loader rows in; web-renderer out).
;; Rows are seeded by scripts/load-book.sh from `borge book export` under
;; data.book (type book-chapter, branch-free data.* namespace -- git stays
;; authoritative for .borg, habitat-book decision 2). This package RENDERS
;; rows; it never parses .borg (one parser, two projections -- borge stays
;; the only parser, decision 3).
;;
;; Kernel-dispatched routes (image/lib/http.ml, no route pins needed):
;;   GET /book                  -> book/page        merged index: borg chapters + package specs
;;   GET /book/chapter/<label>  -> book/chapter-page
;;   GET /book/code/<label>     -> book/code-page
;;   GET /book/course/<suffix>  -> book/course-page notes/outline course doc (kind course)
;;   GET /book/<pkg>            -> spec/book-page   (kernel fallthrough, unchanged)
;;   GET /book/pkg/<pkg>        -> alias of /book/<pkg>
;;
;; Registers (decision 1 -- mode is a render flag, never a document fork):
;;   reader (default): prose/headings/code/examples only.
;;   ?mode=workshop:   + status badges, verify blocks, agent notes,
;;                     untracked lines, unknown-node listings.
;;   Drift holes stay visible in BOTH registers (raw parse-failure
;;   listings, unresolved binding tokens).
;;
;; Depends (boot-seeded): std (string-split), html, list. The binding-token
;; machinery is REUSED from spec when loaded (spec/token-binding?,
;; spec/binding-resolves?) -- the proven drift renderer is inherited, not
;; forked; without spec, prose renders plain (escaped) and everything else
;; works. Example blocks post to /book/eval-example -- the run button goes
;; live with the example-eval prim (habitat-book eval-examples, P2.3).

;; ------------------------------------------------------------------ prose
;;
;; DECISION (2026-08-30, P2.2 dogfood -- obituary): this section first
;; rendered prose with an interpreted per-word pipeline (book/split-piece
;; + book/piece-html via list/map, calling spec/token-binding? and
;; spec/binding-resolves? per word). That cost ~300 interpreter steps per
;; word -- a 12.7k-word chapter needed ~4M steps against the 100k-step
;; page budget, so every chapter page died with "budget exceeded". The
;; per-word work now lives in TWO kernel scans (pure/prims_pure.ml):
;; (prose-tokens s) collects UNIQUE token-shaped cores in one OCaml pass;
;; (render-tokens s resolved holes) renders one paragraph in one pass.
;; Resolution STAYS in Nopales via spec/binding-resolves? (function-source)
;; at O(unique tokens), not O(words) -- the drift decision is still made
;; by the proven spec machinery. The kernel shape test mirrors
;; spec/token-binding?; spec/ keeps the authoritative definition -- keep
;; the two in lockstep (parity-tested in image/test/primitives_test.ml).
;; book/split-piece + book/piece-html + the has-prefix?/has-suffix?
;; helpers are retired with this change.

;;
;; habitat-book.course-documents: a course is a NOTES/OUTLINE doc (slug
;; course/<suffix>, kind course -- the spec/<pkg> slash-slug pattern)
;; whose reading nodes reference chapter labels -- compose, never copy
;; (decision 5). The renderer assembles the doc's outline into an
;; ordered reading list over the seeded chapter rows; the chapter rows
;; themselves never move (data.book.ch.* stays a chapter's ONE home --
;; two courses referencing one chapter duplicate nothing in the tree).
;; A reading node's body starts with a `chapter: <label>` line (the
;; machine reference, book/label-safe? shape); the rest renders as
;; description prose. Status badges show in BOTH registers here: the
;; reading list is itself a status view (spec smoke), unlike
;; chapter-index rows (workshop-only).

168 libs/forge/lib.pp

```
;; package forge -- executable spec graphs as habitat data.
;; Spec: borge/forge.borg. Load: (load-library "forge") or load-string.
;; Depends on: list (foldl/filter/map), notes (log/issues), and kernel prims
;; (read-string, forge-effects, deftype, create/update/get/rows, dict-*).
;;
;; The borge discipline as a living graph: a spec is a tree of typed nodes,
;; each node carries a machine-checkable victory condition, LLM drafters fill
;; leaves bottom-up along a computed frontier, mechanical checkers flag
;; anomalies, and the human approves each level before the descent continues.
;;
;; Exports are prefix-convention (forge/*). See borge/forge.borg for the
;; design rationale: victory conditions are the artifact, code is a cache;
;; planning is a computation (free-vars), not an LLM judgment; mechanical
;; flags run before any human is asked to judge.

;; ============================================================
;; TYPES (graph-model)
;; ============================================================
;; Placement: data.shared.forge-* (outside branch lenses) per one-tree
;; branching-interaction -- same argument as jobs: the loop (host identity)
;; mutates node rows regardless of who drafted.

                "I'm super excited about what has emerged with Pricklypear.
    Pricklypear is the result of a kind of long, meandering journey. I see
    a lot of these cactus on my hike. In the middle of the desert, they
    are common, they are prickly, and they bear delicious fruit. I've also
    been told you can use them to harvest water kefir yeast, but I've yet
    to confirm this.")
              (html/p
                "I quit my development job and now work at a dentist office
    and a restaurant. But I just can't seem to stop coding. For a while I
    was trying to make the ultimate \"CRUDmonkey\" platform. Basically, I
    spent a lot of time with half baked designs trying to reinvent web
    frameworks. Then, I became totally taken with the idea of a tree-based
    structure editor.")
              (html/p
                "My background is largely as a python CRUDmonkey, hence my
    interest in reinventing frameworks. I did a lot of data processing
    elbow grease work. I was CTO of a 13 person startup for a while. When
    I left that job I was pretty burnt out. I didn't think I enjoyed
    programming, but I still was obsessed with the idea of maybe I could
    make it easier.")
              (html/p
                "Then I found OCaml. Functional programming did it for me,
    man. It was like learning to program all over again. I started
    learning about all the things I had basically ignored as a python guy.
    I learned about compilers, low level languages. I took a freelance gig
    doing static analysis on IBM HLASM assembly language.")
              (html/p
                "The only thing I really wanted from code? I wanted to
    build my dream zettelkasten. I just wanted a good notes app for my
    bible study. First I built a bible mode in Obsidian with markdown
    files. But as soon as I tried to get Strong's Concordance in there, I
    absolutely hit the limits of what Obsidian could do. Then, I decided
    to switch over to elisp. LLMs were barely functional at this time, and
    they were really bad at lisp. This was the \"copy and paste from
    ChatGPT\" era. My emacs / org-roam zettelkasten worked amazingly.
    Honestly, I love emacs and I love org-roam. Absolutely beautiful
    pieces of software. I also love the sense of calm that I get with
    emacs software. I pulled up this bible app in emacs 4 years later and
    it just... worked. Amazingly. None of the constant churn of the JS
    ecosystem.")
              (html/p
                "OK, so then I got into OCaml, and I was very anti LLM.
    They didn't work, they made you dumb, they were a scam, yada yada
```

```
      yada. So I built myself a bible app, all by hand, in OCaml / Dream. I
      had a great time with this. I felt like I probably learned more about
      Dream than I did OCaml, but that's how I felt when I first learned
      Python also.")
39              (html/p
40                "Then I took a gig with some guys who were doing IBM
      mainframe LLM stuff. I started coding in TypeScript (which i had never
      really used), right around the time when the LLMs got really, really
      good. Like November of 2025? I saw a massive increase in their ability
      to compose and build code.")
41              (html/p
42                "Then I went deep. I started building harnesses,
      orchestrators, I did the full LLM psychosis thing. I eventually
      settled on my Borge architecture. Without going too deeply into it,
      it's a DSL for defining spec and a series of CLI tools to get agents
      to implement, review, and build out that spec. I'm not sure it's any
      more efficient but it seems to work super well for me.")
43              (html/p
44                "So then one day I had the brainwave. Can I make an
      interpreted lisp where the functions are stored in postgres? The agent
      assured me I was a genius yet again, but I had a good feeling about
      this one. I had the LLM draw out my Borge spec, and then started a
      ralph loop. I think it went for like, 25 iterations? It ran for 4 days
      and it crashed a couple times and I think I maxed out three different
      providers. It used a lot of tokens. I got an email from one of my LLM
      providers the next day letting me know they were tripling their
      costs.")
45              (html/p
46                "When I started playing with it, I actually couldn't figure
      out how to use it at first. I had the agent draw up a intro guide.
      Then I realized that not only did it work, I could write language
      functions to the database, but that also those functions were working
      as web endpoints. I realized I had a whole framework.")
47              (html/p
48                "It worked so well. I built a couple apps on top, it was
      effortless. I plugged an LLM into the system. Once I prompted it to
      realize Pricklypear was not a cactus in this scenario, it completely
      understood the harness it was in and it just... started writing
      functions. I couldn't believe it. Then I gave my local LLM access to
      the full REPL, and I realized I wouldn't ever have to build an API or
      CLI interface for agents ever again.")
49              (html/p
50                "I'm delighted by this. I have wanted a Smalltalk type
      environment since I learned about what that was. But by incredible,
      happy accident, I also got my brand spanking new web framework, and I
      also got my tree based editor. I honestly feel, I don't need any more
      software. I'd be good. If I had my druthers, I would just work on this
      in private and read Functional Programming papers and Alonzo Church in
      my hammock for the next 5 years while I dogfood this thing. But, you
      know, \"building in public\" and all that.")
51              (html/p
52                "I'm hoping some people are as thrilled and inspired by
      this as I am. Maybe the code is useful, or maybe just hearing about
      the concept is enough to inspire people. Or maybe, and this may be
      more likely, nobody will give a crap. I don't know where LLMs will go
      in the future, but I am really happy right here."))))

                "Alright - I'll talk a little bit about what I think
    Pricklypear is good at, and where I see it going")
              (html/p
                "A lot of people have talked about how incredible Lisp is.
    Personally, I'm not totally sold. Don't get me wrong, lisp is
    wonderful. But I think for larger projects you just need static
    typing. I didn't like static typing for a long time, I totally get it.
    But for medium or big projects, I just don't know how you do big
    refactors without it.")
              (html/p
                "That said, I think Lisp is like Ruby a lot, it's a
    beautiful and expressive language. So this is a lisp machine. And I
    think it's good for the same types of programs that Ruby is good at.
    So I did my best to clone Basecamp, hah.")
              (html/p
                "Having an agent work with a REPL is incredible. I mean,
    it's spectacular. They can define functions. They can read and execute
    individual functions. They can build functions inside out or bottom
    up. They can build them top down. They can SSH in remotely and access
    the REPL while they're developing. It's pretty tight.")
              (html/p
                "I don't think any other architecture can match Pricklypear
    for building web apps, and I honestly don't think it's even close. All
    of those LLM marketing idiots telling you about on-demand self healing
    software? Hey, this is it. It's right here. I don't think you can do
    this with any other stack? Maybe like erlang or something.")
              (html/p
                "The future I see for Pricklypear or something like it is
    enabling LLMs to build on demand software for small and medium
    businesses. I don't even think you need to have a Pricklypear guy on
    staff? I mean you could, it'd probably help. But I think literally
    users can ask for features and they will be deployed. I've had some
    trouble getting the built-in agent to build out like a whole app from
    start to finish, but it can certainly add features. And that loop is
    closing fast.")
```

```
            (html/p
              "I'm biased and deep in AI psychosis, but I'm telling you this is a much bigger leap than OpenClaw. Oh, you put your little crab agent inside a chat bot? Guess what? Mine lives inside a language which he is developing himself, and that language is also a fully baked web app. (Sorry, OpenClaw is brilliant, but I had to. You'll understand when you login the first time.)")
            (html/p
              "Let's talk roadmap. I'm going to dogfood this thing for a while. Maybe some other people will do something similar. I don't really feel any obligation to build anything for anybody else. Get your own! But, I would like to get this thing to the point where it's functioning as a self contained unit, and like, my dad could hop on it and he wouldn't have to learn anything about Lisp Machines in order to use it. I think this is feasible. It's just a weird little platform to build apps on.")
            (html/p
              "I'm hoping to get those apps fleshed out a bit. This is my new homelab center. I'm moving my life onto this thing. It's too good not to. So I'd like for those apps to feel really really good. Currently, they do not feel great. They are not cozy. I want calm, and I want cozy. Even though I can change these apps every day - I want to run them without changes for 5 years.")
            (html/p
              "I initially spec'd this out to run on MirageOS, but we've scrapped that for now. I would like to make this happen eventually. For now, I remain an OpenBSD guy. If you want Linux compatibility, make your agent do it. (I use Arch for development, btw). So I think self contained image is a priority.")
            (html/p
              "I would like to get some academic grounding on building this Lisp out. I don't know nothin about languages. Seriously. I just added floats to this thing. Also I think the language itself is called Nopales, but that isn't reflected anywhere right now. There is some sort of rudimentary effects system. I have no idea how it works. I don't really understand the subtleties of async, and the OCaml landscape is pretty confusing.")
            (html/p
              "On a similar note, I'd like to get some education on formal proofs in software. I think that it is absolutely work spending some time trying to add formal verification to the OCaml outershell of Pricklypear. Lisp gives a great surface for the LLM on top, and I'm perfectly happy with a little jank there, but the core really should be incredibly stable.")
            (html/p
              "I want to really polish up the node editor and the code editor. It should be a first class experience. Keyboard shortcuts, node navigation. I want it to feel as good as vim.")
            (html/p
              "I'd like to see local-first LLMs, too. You really don't need much here. And the way it's designed, it would plug right into a local agent. That local agent really wants to generate his own lisp functions using a recursive bottom up function generator call!")
            (html/p
              "OK, that's enough for now. This is about as much sharing as I do, generally speaking. I guess I could get on Twitter and try to shill this thing but I think I'd rather just build it instead."))))

```
(** Pricklypear Lisp -- AST.

    The AST IS the source (homoiconicity). Function bodies are stored as
    JSONB rows in [function_defs.body], parsed back into [expr] values by
    the reader and evaluated by [Eval].

    Per spec [lisp-interpreter.ast]: this is a Scheme-flavored Lisp-1
    (lexically scoped, first-class closures, primitives dispatched by
    name through a table the IMAGE layer registers at boot).

    The interpreter proper is PURE: it takes an env and an expr and
    returns a value or raises an [Interp_error]. No I/O here. Side
    effects go through [Prim] calls, wired to real Postgres/HTTP by the
    image layer. *)

(** A reference into the persistent store. Carries its target type so
    the interpreter can verify derefs at call time before querying. *)
type type_name = string
type id = string  (* uuid-ish; opaque to the interpreter *)

type expr =
  | Var of string
  | Lit of value
  | App of expr * expr list
  | Let of string * expr * expr
  | Letrec of (string * expr) list * expr
  | If of expr * expr * expr
  | Lambda of string list * expr
  | Prim of string * expr list
  | Seq of expr * expr
  | Quote of expr
  | Define of string * expr   (* top-level binding *)

(** Values are what evaluation produces. The interesting cases are
    [VRef] (a tagged reference into the store, so values can point into
    the persistent object graph without copying it) and [VLambda]
    (closures capture their defining env). *)

     interns *)
  | VThunk of thunk_cell ref       (* memoized recipe; forced at
     Env.lookup *)

(** A not-yet-evaluated binding body (lisp-interpreter.lazy-env-thunks).
    The payload carries its OWN evaluator so the pure kernel never
    decides HOW a body runs: pure hosts force under [Eval]'s table,
    the image forces under its prim rim. Memoization covers failure
    too -- a body that raises once replays the exception, it does not
    re-run (and re-pay) on every touch. [Forcing] marks an in-flight
    force so self-referential cycles raise instead of diverging. *)

```
(** Pure structural diff over [Ast.expr] trees.

    Consumer: [branching.diff] -- [Store.diff_branches] feeds the parsed
    from/to bodies of a modified [function_defs] row into [diff] so the
    /diff page can overlay the delta tree on [Ast_html.pp_expr_html].

    No I/O, no Postgres -- tests with [dune runtest lisp] alone, like
    reader / eval / env.

    Semantics authority: [branching.diff]. This module is the pure
    walker (lisp-interpreter.ast-diff), NOT the surface prim -- a
    programmatic [(diff-ast name from to)] prim is explicit v2.

    Non-goals (v1, per branching.diff): rename detection (a bound-var
    rename surfaces as Replaced at the binding site AND every reference
    site), alpha-equivalence (bound names are NOT normalized), and
    param-order is a *positional* child delta, not "renamed params". *)

(** ---- Stepping / trace debugger (borge/remote-eval.borg stepping) ----

    The LLM-debugger substrate. eval runs in a client process; stepping
    is PURELY a client concern -- the server never learns a breakpoint
    fired. The data plane still crosses the wire exactly as a fast eval
    would: pure compute stays local, every prim call that is not a local
    pure prim is forwarded via [transport], and its value/error returns
    to the paused continuation.

    [trace] is a ONE-PASS trace: it runs [src] once under a proxy-style
    rim and records an ordered, interleaved event list whose [Local]
    entries count the local pure eval steps since the last wire crossing
    and whose [Remote_ok]/[Remote_err] entries are the remote prim round
    trips (distinguished from local steps). The [Breakpoint]/[Step]/
    [Continue] driver walks that already-produced trace (presentation
```

```
    stepping): it NEVER re-evals, so side effects are never repeated and
    the wire is never re-crossed -- stepping is a client concern by
    construction (remote-eval.borg hard-constraints). *)

(** One trusted event in a [trace] run. [Local n] = n local pure eval
    steps since the last wire crossing (0 between two adjacent round
    trips); [Remote_ok (name, value)] = a remote prim round-trip
    returned [value]; [Remote_err (name, err)] = it relayed an error. *)

240 lisp/lib/reader.ml

```
(** Pricklypear Lisp -- S-expression reader.

    Parses surface s-expression syntax -> Ast.expr. The AST IS the
    source (homoiconicity): a function stored as JSONB is its AST, and
    the s-expr syntax is one of several possible editors (along with
    the htmx tree-editor that edits the AST directly).

    Per spec [lisp-interpreter.reader]:
      - Standard s-expressions: (foo bar baz), 'symbol, "string", 123,
        #t, #f, ()
      - String escapes: named (n/t/r/backslash/quote/apostrophe),
        three-digit decimal byte (\\ddd), unicode scalar (\\uXXXX,
        UTF-8 encoded; lone surrogates rejected); other backslash-X
        is forgiving (literal X)
      - Comments: ; to end of line
      - Docstrings: a leading string in a body position (deferred; reader
        just produces the AST, docstring extraction is eval-time)
      - Special forms [lambda/let/letrec/if/define/quote] are recognized
        at EVAL time, not read time -- the reader produces plain App
        nodes; eval dispatches them.

    The reader tracks line/col for error messages. *)

242 lisp/lib/route_gate.ml

```
(** Public-route handler effect gate (pure).

    Decides whether a handler may be published as a public route by
    inferring its effects from the in-memory env (synchronous, fresh)
    and checking them against the public-route allowlist. Fail-closed:
    an unknown or non-function handler is DENIED, never silently allowed.

    Pure: no Lwt, no DB. The image's [Session.check_public_handler]
    (session.ml) delegates here so the gate is unit-testable without
    Postgres.

    Addresses BORGE-1785212463 / BORGE-1785212603: the previous gate read
    function_defs from the store (stale after the define persist race)
    and DEFAULTED TO ALLOW when the handler was absent -- so a typo or an
    eval-order race silently published a route with no effect check.

    BORGE-1785212882: bodies are macroexpanded before [Effect.infer] so a
    macro cannot hide WriteDb/Publish/etc. from the allowlist. Expansion
    uses [Eval.macroexpand_expr]; [Effect.infer] stays pure. *)
open Ast

251 lisp/test/stepping_test.ml

```
(** Tests for the remote-eval stepping/trace debugger (borge/
    remote-eval.borg stepping, campaign 7.3): Explain.trace /
    Explain.stepper / breakpoints. PURE tests -- a mock transport stands
    in for the remote prim round trip, no Postgres, no HTTP.

    These verify the three stepping verify-stanzas:
      - a breakpoint on a def/prim pauses local eval mid-expression and
        the data plane (prim calls) still crosses the wire and returns
        (the breakpoint fires ON a Remote_ok/Remote_err event);
      - the server is unaware a breakpoint fired: the mock transport
        observes EXACTLY the calls the fast eval would make -- one per
        proxied prim, never extra, and presentation-stepping never
        re-evals so the wire is never re-crossed;
      - a trace shows local pure steps interleaved with remote prim
        round trips, distinguished ([Local n] vs [Remote_ok]). *)

257 migrations/003_data.sql

```
-- Pricklypear migration 003: generic data row storage.
--
-- Per spec [storage.types]: user-declared types in Lisp (registered via
-- (deftype 'name fields...)) are stored as type_defs (migration 001).
-- Actual data rows of those types live HERE in `data_rows`.
--
-- Data rows are shared across branches (per spec [branching.data]):
-- fork/merge only copies CODE (functions/types/views), not data.
-- All branches see the SAME data rows. Writes go straight to main;
-- reads don't need the recursive-CTE branch walk.
--
-- Design choice for v1: rows are stored as a single jsonb {fields}
-- document per row, keyed by (type_name, id). This avoids generating
-- one PG table per Lisp-declared type (which would require DDL at
-- runtime and break the additive-migrations_only rule). Future work:
-- if a type is hot enough to warrant its own table, a migration can
-- hoist it (the Lisp layer wouldn't change).
--
-- Per spec [workflow.conventions]: SERIALIZABLE transactions by
-- default for mutations. Additive-only migration. No ORM.

CREATE TABLE IF NOT EXISTS data_rows (

267 migrations/013_data_user_scoping.sql

```
-- Pricklypear migration 013: user-scoped datum paths + RLS floor.
--
-- Per spec [one-tree.branching-interaction] /data DECISION (2026-08-02)
-- and [one-tree.migration-plan] Phase 2b. Closes BORGE-1785693032.
--
-- Datum paths become:
--   per-user  data.u.<user_enc>.<type_enc>.<id_hex>
--   shared    data.shared.<type_enc>.<id_hex>
-- A session sees exactly its own data.u.<user>.* plus data.shared.*.
-- No branch id in datum paths. data_rows stays physically (additive-only);
-- tree_data_rows view + CRUD prims confine; RLS on tree_nodes is the floor.
--
-- Seed types (visible to every session via data.shared):
--   bible-verse, bible-book, bible-interlinear, strongs-entry
-- All other existing rows backfill under data.u.<author_enc>.* keyed off
-- data_rows.author / tree_nodes.author. Unknown/empty author ->
    data.u.unknown.
--
-- Notes hierarchy (kind folder|note|heading under data.note.u.<user>.*) is
-- NOT kind=datum and is exempted by the RLS kind <> 'datum' clause.

--
    ------------------------------------------------------------------------
-- Helpers: datum id is ALWAYS the last ltree label (uuid hex).
-- Works for data.<type>.<id>, data.u.<user>.<type>.<id>,
    data.shared.<type>.<id>.

270 migrations/016_seed_single_source.sql

```
-- Pricklypear migration 016: single source of truth for the seed-type list.
--
-- Seed corpus types (shared under data.shared.*, visible to every session)
-- were previously listed in three places and drifted (see log/issues/
-- i-seed-list-3copies-2026-08-12): the SQL predicate tree_is_seed_type, the
-- crud.ml visible_sql IN-list, and the OCaml Tree_store.seed_types array.
-- Migration 013/014 already moved these into one SQL predicate; this step
-- makes THAT predicate derive from a single authoritative array function,
-- tree_seed_types(). The OCaml Tree_store.seed_types constant stays as the
-- pure mirror needed by the DB-free `node-path` prim; a boot-time check
-- (Tree_store.verify_seed_types) flags any divergence from this authority.

-- The ONE place the type-name list lives on the server side:

271 migrations/017_branch_generation.sql

```
-- Pricklypear migration 017: branch generation counter for definition-cache
-- invalidation (remote-eval.borg caching subsection).
--
-- The remote Nopales client caches function/type/route defs locally under
-- a (branch_id, generation) key. A write anywhere in a branch's ancestry
-- must bump a monotonic generation counter so the client's next cheap
-- cache-check round trip observes the bump and reloads. This is
-- materialized-view invalidation in small costume: ONE counter per branch,
-- not a hash per def.
--
-- We use a small branch_generations table keyed by branch_id (kept apart
-- from the core branches row and the one-tree lens registry). Triggers on
-- the branch-scoped code tables (function_defs / type_defs /
-- view_bindings) bump the generation of the branch actually written. The
-- reverse one-tree mirror (tree_nodes -> scaffolding tables, migration 009)
-- shares these tables, so a tree-as-truth write still flows through these
-- triggers. promote/merge write function_defs/view_bindings, so those
-- bumps are covered by the same triggers (no separate promote/merge hook).
--
-- data_rows are BRANCH-FREE / shared across every branch (migration 003
-- branching.data). A data write is therefore visible to every branch's
-- ancestry, so we bump the ROOT branch(es) (parent_id IS NULL); the
-- ancestry-walking current_generation query then surfaces that bump to
-- every descendant. (The client does not cache hot data_rows -- placement
-- keeps those remote -- but the counter remains truthful for the shared
-- data plane.)

```
-- Pricklypear migration 018: tree-time versioned-leaf table.
--
-- Per spec [tree-time.migration-018] (campaign 5.0 plan pass, pinned
-- schema contract). This ADDS the append-only history table for the
-- generation axis on the one tree: (branch_id, path, gen) -> node. It is
-- pure Phase 1 additive foundation -- nothing reads it yet (the scaffolding
-- mirrors + tree_nodes stay the source of truth through Phase 2's
-- flag-guarded read switch), and the write path only appends version rows
-- once tree_store.ml (5.1) grows its dual-write shadow.
--
-- Path grammar matches tree_nodes (migration 009):
--   fn     b.<branch_id>.fn.<name>
--   type   b.<branch_id>.type.<name>
--   route  b.<branch_id>.route.<route_b64url>
--   datum  data.<type_name>.<id>          (branch-free)
--
-- This file is strictly ADDITIVE + idempotent + image-applied (registered
-- in schema_migrations so the runner will not re-apply).

-- tree_generations: the TREE-WIDE data head counter (branch-free paths).
-- code paths (b.*) use branch_generations (017) as their head instead, so
-- this row serves only branch-free data.* writes. One monotonic bigint;
-- the 017 root-row bump discipline generalized to one row (the
-- local-first.sync merge clock).

273 migrations/019_tree_version_shadow.sql

```
-- Pricklypear migration 019: tree-time Phase 1 dual-write shadow.
--
-- tree-time.versioned-leaves (5.1): the write path appends a version row
-- to tree_versions (migration 018) IN ADDITION to every tree_nodes write.
-- The dual-write is implemented as an AFTER trigger on tree_nodes -- not as
-- per-function appends inside tree_store.ml -- for ONE decisive reason:
-- MIRROR PRESERVATION (one-tree.bl-blast-radius / this chapter's
-- versioned-leaves details doc). A scaffolding-table writer (promote/merge
-- writing function_defs/type_defs/view_bindings/data_rows) reaches the tree
-- through the 009_tree.sql tree_mirror_* triggers; a trigger on tree_nodes
-- shadows EVERY such write source (tree_store.ml direct writes AND mirror
-- writes AND reverse-mirror writes) with a single, uniform mechanism. A
-- tree_store.ml-only dual-write would have to be re-wired through every
-- mirror trigger to keep the scaffolding-writer and tree-writer histories in
-- lockstep; the node trigger gets that for free.
--
-- Semantics (per tree-time.migration-018):
--   - gen source per path class: b.<branch>.* code paths bump
--     branch_generations (017, per-branch); branch-free data.* paths bump
--     the tree-wide tree_generations row (018). The append takes gen+1 and
--     bumps the counter -- the counter never moves backwards (verify script
--     check #4).
--   - delete never DELETEs: it appends a TOMBSTONE row. The tombstone body
--     uses the SAME reserved marker tree_versions_tombstone() returns
--     ({"_tombstone":true}) so head helpers and readers agree on one marker.
--   - gen-window partitions (>=1000) are created lazily via
--     tree_versions_prepare(); the base window tree_versions_gen_0 comes
--     from migration 018.
--
-- This migration is STRICTLY ADDITIVE + idempotent + image-applied
-- (registered in schema_migrations so the runner will not re-apply).
-- It is the shadow only; nothing reads tree_versions until Phase 2
-- (reads-as-of-gen, tree-time.reads-as-of-gen) flips the PP_* flag.

-- Lazily create the gen-window partition for [gen] (windows >= 1000 only;
-- the base window gen_0 exists from 018). The retention worker (gc) also
-- uses this to pre-create windows. Skipping wn=0 avoids an overlap with
-- tree_versions_gen_0 (partition-of = tree_versions FOR VALUES FROM
-- MINVALUE TO (1000); a partition FOR VALUES (0,1000) would collide).

274 migrations/020_tree_version_echo_guard.sql

```
-- Pricklypear migration 020: tree-time mirror-echo guard for tree_version_append.
--
-- tree-time.versioned-leaves (5.1/5.2): the 019 AFTER-trigger on tree_nodes
-- shadows every tree_nodes write into tree_versions. But the one-tree mirror
-- arrival means a single LOGICAL write can touch tree_nodes TWICE:
--
--   tree-first writer -> tree_nodes (authoritative, gen N)
--     -> tree_from_nodes (reverse mirror, deferred) -> scaffolding table (*_defs /
--        data_rows) -> tree_mirror_* (forward mirror, constraint) -> tree_nodes echo
--        (same content, recomputed hash; pg.tree_mirror guard stops the ping-pong)
--
-- The echo carries the same content body/author/kind/type_name (only the derived
-- `hash` -- sha256 over a differently-normalized body text -- is recomputed by the
-- mirror). Without a guard, 019 double-counts every logical write as two (path, gen)
-- rows and bumps the head counter 2x.
--
-- This migration REFINES tree_version_append(): on UPDATE, when the new row's
-- content (kind, type_name IS NOT DISTINCT, author, payload->'body') is unchanged
-- from OLD, it is a no-op mirror echo -- return NEW BEFORE allocating a gen or
-- inserting a version row. This is the "mirror head-gen filter" of
-- tree-time.projections (every appended gen is a real new head; echoes are not
-- versions). Authoritative writes -- tree-first (store writes tree_nodes directly)
-- AND table-first (a scaffolding write mirrored INTO tree_nodes with changed
-- content) -- always change body/author/kind/type and land exactly one version row.
--
-- Additive: CREATE OR REPLACE on the 019 function; no table changes. Idempotent via
-- the 019 trigger (unaffected) -- re-applying this only re-replaces the function.

-- The node-level AFTER trigger body, with the mirror-echo no-op guard.
CREATE OR REPLACE FUNCTION tree_version_append()

275 migrations/021__tree__versions__reconcile.sql

```
-- Pricklypear migration 021: tree-time head reconciliation tool.
--
-- tree-time.phase-1 (5.1/5.2): the dual-write shadow (019 trigger) writes
-- a tree_versions row per tree_nodes write, including a TOMBSTONE on delete.
-- A delete-then-recreate cycle whose re-create did NOT re-shadow (historical
-- trigger-iteration residue, or a writer that inserted tree_nodes without the
-- append trigger attached) leaves a LIVE tree_nodes row beneath a TOMBSTONE
-- newest version row: the versioned head says ABSENT while the live row says
-- PRESENT. Per tree-time.projections, that is NOT head-equivalent and the
-- Phase-2 read switch must not run until it is.
--
-- This migration ADDS an idempotent reconciliation function (no data is
-- destroyed, nothing is rewritten in place) that heals exactly that class:
-- for every shadowed LIVE tree_nodes row whose newest version row is a
-- TOMBSTONE, it appends a FRESH non-tombstone version row holding the LIVE
-- tree_nodes content (the live row is the authority), allocating the head
-- gen exactly as the 019 trigger does (branch_generations for b.* code paths,
-- tree_generations for branch-free data.* paths, gen-window partition lazily
-- created). The live tree_nodes row is untouched. Idempotent: a healed row no
-- longer matches the cursor, so rerunning it heals zero.
--
-- It ALSO repairs head COUNTERS (
--branch_generations / tree_generations): a branch whose
-- branch_generations.generation is below the max live code-gen of its own
-- live code version rows is a head-coordinate regression (the next write
-- would collide or regress); the counter is raised to that max. This is the
-- same restore-by-repair discipline, and is what makes the Phase-1 verify
-- gate's head-counter check pass after a reconcile.
--
-- Run it, then the Phase-1 verify gate
-- (scripts/verify_tree_version_shadow.sh) must PASS.
--
-- Additive (CREATE OR REPLACE FUNCTION only) + idempotent + image-applied.

276 migrations/022_tree_retention.sql

```
-- Pricklypear migration 022: tree-time GC -- retention policy + retention worker.
--
-- tree-time.gc (5.3): retention is the three existing pieces composed:
--   (1) PARTITIONING -- tree_versions is already partitioned by gen-range windows (018 base gen_0 + lazily-created tree_versions_p{wn} windows
--       >= 1000 from 019). Physical removal is DROP PARTITION -- instant, no
--       vacuum scan, PG-native.
--   (2) RETENTION POLICY IS HABITAT DATA -- this migration adds a policy
--       TABLE (tree_retention_policy). Policy rows declare per-path-class
--       retention (code paths keep all -- the audit trail; data paths per-type,
--       default keep-everything until a policy row exists). The jobs runner
--       (migration 015) executes the retention worker.
--   (3) ROLLUP, NOT SILENT LOSS -- before a window is dropped, surviving
--       state collapses to a CHECKPOINT row at the window boundary gen, so
--       reads as of ancient gens still resolve (to the checkpointed state)
--       and head reads never notice. "Nobody gets everything forever -- the
--       audit claim survives at coarser grain."
--
-- PHASE 4 (tree-time.coexistence-plan): this is the gate that flips the gc
-- chapter to implemented -- "the retention worker runs on the jobs runner."
--
-- STRICTLY ADDITIVE + idempotent + image-applied (registered in
-- schema_migrations so the runner will not re-apply).

--
    ------------------------------------------------------------------------
-- Policy as habitat data. path_class: 'code' | 'data'. type_name NULL =
-- whole path class. keep_windows = number of newest 1000-gen windows to
-- retain; windows entirely below the retention floor are rolled up + dropped.

277 migrations/023_data_lens.sql

```
-- Pricklypear migration 023: versioned user-keyed data -- data lens namespace.
--
-- Spec: one-tree.borg branching-interaction (2026-08-23 plan-phase proposal,
--       now make). Adds an OPT-IN data.l.<lens>.<user>.<type>.<id> path for
--       deliberate data forks that diverge and merge back. The default
--       data.u.<user>.* stays single-head and branch-free; data.l.* is the
--       explicit version axis.
--
-- What this migration does:
--   1. tree_datum_path gains a ~lens_name parameter; when set, the path is
--      data.l.<lens>.<user>.<type>.<id> instead of data.u.<user>.<type>.<id>.
--   2. tree_data_rows view + RLS policy allow data.l.<lens>.<user>.* reads/writes
--      for the owning user (same path-prefix confinement as data.u.*).
--
-- What this migration does NOT do:
--   - No data migration of existing rows (new path shape is opt-in only).
--   - No notes path migration (that is a separate make task; see notes.borg).
--   - No tree-time generation tracking for data.l.* (follows in tree-time make).

--
    ------------------------------------------------------------------------
-- tree_datum_path: add optional lens_name parameter.
-- When lens_name is non-empty, path is data.l.<lens>.<user>.<type>.<id>.
-- The DEFAULT '' preserves the existing data.u.<user>.<type>.<id> shape for
-- all existing callers that don't pass lens_name.
-- DROP the old 3-arg signature first to avoid a non-unique overload
-- (CREATE OR REPLACE with a different arg count creates a new function,
-- not a replacement). DO block for PG portability (no IF EXISTS on DROP).

278 migrations/024_branch_base_gen.sql

```
-- Pricklypear migration 024: branch base_gen -- the merge-base coordinate.
--
-- Per spec [branching.branch-status] (plan pass pinned; tree-time consumer).
-- A branch records the parent's head generation (branch_generations,
-- migration 017/019) at fork time. Combined with the append-only
-- tree_versions history (018-021), "value of path P at base_gen" is a
-- READ, so git-style clean / ahead / behind / diverged / synced status is
-- a derived hash comparison, not a name-presence join.
--
-- base_gen ADVANCES when a merge lands the branch into its parent (git's
-- moving merge-base). promote deliberately does NOT advance it: selective
-- pins stay visible as `synced` (the unbind-candidate class) until
-- unbound or merged.
--
-- Backfill: existing branches predate the column, so the true fork point
-- is unrecoverable. Approximation (documented in branching.branch-status):
-- treat the fork as having happened at the parent's CURRENT generation --
-- inherited paths then read clean/behind correctly, and existing own pins
-- classify against today's parent content. Empty children (the dominant
-- shape) are exact under this backfill; full-fork copies whose parent
-- moved since the real fork read `synced` (they are content-identical
-- pins -- which is the actionable truth for the unbind flow anyway).
--
-- Strictly ADDITIVE + idempotent + image-applied (registered in
-- schema_migrations so the runner will not re-apply).

279 migrations/025_sibling_order.sql

```
-- Pricklypear migration 025: sibling-order (one-tree.sibling-order).
--
-- Children get a USER-CONTROLLED ORDER: a nullable rank TEXT column on
-- tree_nodes (fractional-indexing string, Figma/Linear style), carried
-- through the tree-time version shadow so ordering is versioned,
-- diffable, undoable like every other node property.
--
--   - NOT fractional path labels: the path is WHERE a node is; the rank
--     is WHAT SLOT it is in. Rank is mutable without touching identity.
--   - NULL rank means unordered: reads order by
--       rank COLLATE "C" NULLS LAST, path::text ASC
--     so unranked siblings sort after ranked ones, path-ordered among
--     themselves. Existing rows need no backfill; ordering is opt-in
--     per sibling set.
--   - Rank strings are base-36 fractional strings over [0-9a-z] compared
--     as raw bytes (COLLATE "C", with implicit right-padding '0') -- the
--     same alphabet byte order everywhere, locale-independent. Midpoint
--     allocation + rebalance-on-exhaustion live in image/lib/tree_store.ml
--     (write-path detail, not visible in the prim ABI).
--   - tree_versions gains the same rank column and tree_version_append
--     echoes it, so gen-read/undo carry order (reorder is an ordinary
--     versioned write; a rank-only UPDATE is NOT a mirror echo).
--
-- This file is strictly ADDITIVE + idempotent + image-applied (registered
-- in schema_migrations so the runner will not re-apply).

638 (* ---- dict primitives over VStr JSON -----------------------------
639
640    Iteration-14 decision: don't introduce a new VDict value type yet
641    (that would ripple through ast.ml / reader.ml / eval.ml / value
642    JSON round-trip). Instead, (get 'type id) returns a VStr holding
643    the fields JSON; these prims operate on VStr JSON directly so Lisp
644    code can do:
645        (define u (get 'user id))
646        (dict-get u "name")
647        (dict-set u "active" "false")
648    The primitive returns VStr JSON (or VNil if the input wasn't a valid
```

```
   object, or key wasn't found). The underlying parse-and-emit is
   Yojson; the canonical round-trip preserves well-formed objects. *)

(* (dict-get json-str key) -> VStr value | VNil.
   Looks up [key] in the JSON object at [json-str]. Returns the value
   as a VStr (numbers and booleans stringified via Yojson); VNil if
   the key is missing or the input isn't a JSON object. *)

(** habitat-book web-renderer: prose tokenization for binding-token
    links. Both prims are ONE OCaml scan over the prose (Buffer + direct
    char tests, zero interpreter steps) -- the interpreted per-word
    pipeline they replace (book/split-piece + spec/token-binding? per
    word in libs/book) cost ~300 steps per word, so a 12.7k-word chapter
    needed ~4M steps against a 100k page budget. Resolution stays in
    Nopales (spec/binding-resolves? via function-source) but at
    O(unique tokens), not O(words).

    (prose-tokens s) -> list of UNIQUE token-shaped cores in first-
    occurrence order. Whitespace runs (space/tab/newline) separate
    words; at most one leading char from ( [ ' , and one trailing char
    from ) ] , . ; : is stripped as edge punctuation (the retired
    book/split-piece sets, minus \n which is now a separator). The
    token-shape test MIRRORS spec/token-binding? (len>2, contains "/",
    not "->", not "/", no space, not leading "/") -- spec/ keeps the
    authoritative definition; keep the two in lockstep (parity-tested
    in image/test/primitives_test.ml). *)

(* (string-split s delim) -> VList of VStr.
   Matches the libs/std Nopales string-split semantics so libs/hyper runs
   unchanged on hosts that don't load libs/std (the agent): empty/no-match
   -> single-element list of the whole string; otherwise splits on each
   non-overlapping occurrence of delim, preserving empty trailing
   segments. KERNEL PRIM as of 2026-08-30 (habitat-book web-renderer):
   the interpreted libs/std definition cost ~O(n) interpreter steps per
   input byte -- one 3KB prose paragraph blew the 100k-step page budget --
   so std no longer defines it and the image registers this prim
   (string-split moves to the reserved catalog). Empty delimiter returns
   the whole string (the retired std version looped forever there). *)

```
(** Pricklypear -- shared soup/ tree prims (the hypermedia-harness kernel).

    DB-free lambdasoup-based HTML tree prims lifted out of the
    image-only [image/lib/prims_hyper.ml] into this shared pure-prims
    layer so BOTH hosts register the SAME tree prims: the image
    (Postgres corpus) and the agent (local-first lens corpus). Only
    route/dispatch + route/lookup remain host-specific (they touch the
    host's store / routes / request context -- see hypermedia-harness
    request-runner). lambdasoup + markup are deps of this layer.

    Spec: borge/hypermedia-harness.borg (kernel-prims + supported-subset).

    Page/node values are opaque VStr handles into module-global tables
    (same handle-as-id pattern as net_streams). Low-level soup/* prims
    mutate in place; the Lisp layer [libs/hyper] deep-copies
    (soup/page-copy) before each deriving interaction, so pages are
    immutable at the hyper/* surface (free history + diff). *)

(** pp-remote -- a Nopales client process (borge/remote-eval.borg client).

    Embeds the pure lisp interpreter, lazily materializes function
    definitions from a remote branch, and proxies Prim_call effects to
    the image over HTTP. Pure compute stays local; everything else
    crosses the wire to POST /api/prim. The store stays the single
    source of truth -- quit the client, lose nothing but REPL state.

      export PP_URL=http://127.0.0.1:18080
      export PP_USER=admin PP_PASS=admin
      pp-remote '(+ 1 2)'          # one expr, print, exit
      pp-remote                    # stdin REPL

    Flags:
      --image URL    base URL of the image (default: PP_URL / 127.0.0.1:18080)
      --user NAME    basic-auth user (default: PP_USER / admin)
      --pass PASS    basic-auth pass (default: PP_PASS / admin)
      -e EXPR        eval one expr and exit (repeatable)
      -p EXPR        alias of -e (pipe mode)
      --model NAME   provider model (default: AGENT_MODEL / GLM-4.7-Flash)
      --base-url URL provider base URL (default: AGENT_BASE_URL / synthetic.new)
      --mock-script FILE  canned provider replies (test/demo of /chat)

    The LLM provider runs LOCALLY (borge/remote-eval.borg agent-loop):
    the API key is a value read from AGENT_API_KEY (same env the agent
    reads); only the data plane (DB prims inside tool bodies) crosses
    to the image. *)

(** ---- local-first lens (borge/local-first.borg Phase 1) ----

    [--lens DIR] wires [Remote.make ~lens_lookup] so function defs
    resolve from a filesystem JSON substrate BEFORE proxying
    [function-source] to the image -- the offline-first def path. The
    lens root is a directory of node-envelope .json files (one file per
    node, at its tree path) produced by [Lens_store.materialize_*].

    [--lens-pull NAME] (repeatable) seeds the lens from the live image:
    each NAME is fetched via the [function-source] proxy (the resolved,
    closest-wins source) and written as a code node under the lens
    branch, so the substrate is populated and subsequent evals read
    from disk. This is the Phase-1 materialize step done simply --
    online pull, then offline eval. *)

284 remote/lib/def_cache.ml

```
(** remote/lib/def_cache.ml (borge/remote-eval.borg caching).

    The client-side half of the definition cache, keyed
    (branch, generation). The client materializes defs lazily into its
    env (client subsection, [Remote.load_def]); this module is the
    INVALIDATION half: "is my (branch, generation) still current?" is a
    single cheap round trip (two single-counter read prims) -- NOT an
    N-way hash diff over every def.

    KEY. The cache holds (def-name -> (value, source-generation)) and a
    pinned (branch, generation) key. Generation is migration-017
    branch_generations -- the SAME coordinate tree-time reads as-of and
    the (gen-now) prim read (the campaign-7.0 dependency pin): one
    counter, one namespace, no independent version clock to drift.

    INVALIDATION ([check] returns the names to evict from the client
    env so the next reference re-fetches from the writer -- the server is
    the source of truth, the cache never is):
      - Branch is the namespace: a checkout to a different branch
        invalidates the WHOLE cache (every cached name is returned for
        eviction).
      - A generation bump (a write anywhere in the branch's ancestry --
        a promote into main, a define on personal, a data write) marks
        every def loaded before the new generation STALE and returns
        their names for eviction.
      - No writes -> the check round trip returns unchanged-generation
        and returns [] (nothing touched).
    A def-free / pure-compute session never pins a coordinate, so
    [is_active] is false and the round trip is skipped entirely (zero
    HTTP on pure compute).

    TRANSPORT-DRIVEN (proxy rim discipline). This module does zero
    interpretation itself. It reads the two counter prims (current-branch
    + gen-now, both proxyable reads registered on the image) through the
    same [Proxy_rim.transport] everything else uses, so it is unit-testable
    with a mock (no live server). It never writes. It is a cache +
    interpreter, never a source of truth. *)

286 remote/lib/http_transport.ml

```
(** remote/lib/http.ml (borge/remote-eval.borg client).

    The production [Proxy_rim.transport]: POST /api/prim to the image
    over a hand-rolled HTTP/1.1 connection on an Eio flow (plain or
    TLS). No curl -- the agent's [Provider.post_json] is the reference
    pattern; gluten (Httpun_eio.Client) refuses non-socket TLS flows,
    and a 1.1 request/response with `connection: close` is honest.

    Auth is HTTP Basic (user:pass base64), the SAME path /api/eval and
    /api/prim accept on the image. Identity is server-asserted: the
    client only presents credentials; whoami/current-author come back
    FROM the server. The transport returns (value, exn) Result so it
    slots directly into [Proxy_rim.run] -- errors are re-raised by the
    rim via [Prims_pure.error_of_json] so the client sees identical
    exceptions to in-process eval. *)

287 remote/lib/http_ui.ml

```
(** pp-remote HTML surface server (borge/remote-eval.borg surfaces +
    agent-loop).

    A local HTTP server (Httpun_eio) bound to 127.0.0.1 on a random
    port. The pages are NOPALES-AUTHORED htmx fragments on the client
    route table (rendered by Nopales via [libs/html]), dispatched
    in-process through [Remote.dispatch_route]. The eval POST handler
    is OCaml (it calls [Remote.eval] and renders the result via the
    Nopales [eval/result] template).

    The CHAT TURN is the shared agent loop running on THIS host
    (borge/remote-eval.borg agent-loop): provider call local (the API
    key is a value from the environment), tool bodies eval under the
    proxy rim (DB prims cross to /api/prim), streaming as
    multipart/mixed htmx fragments -- the same emitter + Nopales
    fragment templates the agent serves (chat/user-bubble,
    chat/turn-open, chat/think-open, chat/think-token, chat/tool-open,
    chat/tool-line, chat/tool-done, chat/token, chat/error).

    Bootstrap/asset plumbing stays OCaml (per the surfaces scope): the
    vendored htmx assets are baked into the binary ([Assets]) and
    served at /assets/*.js. Sibling of agent/lib/http_ui.ml: the HTTP
    plumbing + GET dispatch + asset serving mirror it; the chat stream
    drives Remote.t instead of Runtime.t. *)

   --boundary + Content-Type: text/html + optional HX-Target/HX-Swap +
   blank + html. Returns `Peer_gone on closed writer so the drain loop
   stops cleanly.

   WRITE WATCHDOG: a client that disconnects mid-stream leaves the
   socket in CLOSE-WAIT -- writes keep SUCCEEDING into the kernel send
   buffer until it fills, then the write/flush blocks FOREVER (and on
   some teardowns gluten stops servicing writes without closing the
   Body.Writer, so the flush callback never fires either way). Race
   the whole write path against a 5s sleep: a healthy part write
   completes in milliseconds; a timeout means the connection is gone
   ? Peer_gone. (Same fix in agent/lib/http_ui.ml, which had the same
   latent hang.) *)

288 remote/lib/lens_store.ml

```
(** remote/lib/lens_store.ml -- borge/local-first.borg local-substrate.

    A local lens is a branch of the one tree whose root lives on a client.
    This module is the FILESPUN SUBSTRATE (local-substrate): a directory
    tree of node-envelope JSON files, one file per node, at its path. It
    also pins the two slices the 8.1 make of lens-model + replication-units
    is concretely responsible for:

      - LENS FORK / NAMING (lens-model). A clone forks the user's current
        branch into a client-owned lens via the EXISTING (fork ...) /
        Store.fork_branch (an empty child branch, parent pointer only).
        [fork_lens_name] builds the <owner>/lens-<device>[-<date>] branch
        name that fork is given (e.g. admin/personal -> admin/lens-laptop-
        2026-08-14). The lens is single-writer; the server never writes into
        it except via sync/merge; local writes are commits whose atomicity
        is the substrate's (rename(2)).

      - REPLICATION UNIT (replication-units). [in_replication_unit] decides
        which node paths travel to a client -- exactly the authorized-read
        subtree: data.u.<user>.* (the user's own rows, full), data.shared.*
        (read-mostly seed), b.<lens>.* (the forked code lens within the
        subtree). Inheritance (defs resolving through branch ancestry) is
        READ-TIME resolution -- the client stores only the lens's own
        overrides, not a per-ancestor copy. Nothing outside the path-prefix
        confinement (the one-tree RLS floor) is offered for replication: the
        client cannot ask for, and the server cannot send, a path the
        identity cannot read in a normal session.

    Substrate interface (the spec pins: path-addressed get/put/subtree-list
    + envelope + hash). [materialize] writes a single node JSON under the
    lens root at its path (one file per node); [get]/[subtree_list] are the
    path-addressed reads; [node_hash] is the content hash (the git-style
    "hash over the canonical body" that sync's three-way-diff keys on).
    Every write is atomic (temp file + rename(2)) -- the single-writer
    atomicity the lens gets WITHOUT a second engine (no SQLite, no second
    query engine; the server stays the index).

    This module is pure filesystem + JSON: no Postgres, no Lwt, no network.
    It lives in the client package (remote/) so the offline lens works even
    when the server is unreachable. *)

(** Content hash over a canonical JSON string -- the node-envelope [hash]
    field, the git-style "hash over the canonical body" that sync's
    three-way-diff keys on. Pure digestif (the same digest family the lisp
    package uses); no image-side dependency, so the client computes hashes

(* ========================================================================
   CODE-LENS + ANCESTRY MATERIALIZATION (local-substrate, 8.2)

   The replication-unit manifest (replication-units subsection) names the
   forked code lens b.<lens>.{fn,type,route,pkg}.* PLUS the branch
   ancestry the lens resolves through (defs resolve through inheritance
   per one-tree tree-model read-time resolution). These helpers complete
   the substrate's coverage of that manifest: the client can materialize
   the forked code lens + record the ancestry chain it resolves through,
   then resolve ANY definition (offline) by walking the chain
   self-first with the same closest-ancestor-wins rule a server-side
   eval of the lens would use (store.branch_chain self-first).

   One file per code node at its b.<branch>.<kind>.<name> tree path,
   exactly like a datum node -- the filesystem stays the only index, and
   sync (3-way tree-diff) keys on the same envelope [hash].
   ======================================================================== *)

289 remote/lib/placer.ml

```
(** remote/lib/placer.ml (borge/remote-eval.borg placement).

    Hybrid placement: decide, per expression, whether to evaluate
    LOCALLY (under the proxy rim -- pure compute stays local, prims
    proxy individually) or to POST the expression REMOTE (/api/eval
    wholesale -- one round trip for the whole thing).

    Rules (correctness first, then latency):
      1. (with-transaction ?) ? REMOTE, hard. A transaction holds
         (select-for-update ?) locks across prims in its body; locks
         cannot span HTTP calls. Relaxing this corrupts the store.
      2. prim-call count above a configurable threshold ? REMOTE, to
         avoid N prim round trips where one eval round trip suffices.
      3. zero prim calls ? LOCAL (pure compute, no wire).
      4. otherwise ? LOCAL (proxy prims individually; the common case
         for definitional/interactive work).

    The decision is visible: [placement] carries a human-readable
    reason so the user can see WHY an expr went remote (no silent
    boundary). The walker is conservative: it counts apparent prim
    calls by AST shape (App of Var name where name is not a known
    special form / local pure prim definition site). It does NOT eval,
    so a name that resolves to a lambda is still counted -- that's the
    right bias for a latency heuristic (over-counting pushes remote,
    which is the safe direction). *)

290 remote/lib/proxy_rim.ml

```
(** remote/lib/proxy_rim.ml (borge/remote-eval.borg client).

    A second rim for the SAME [Control.Prim_call] seam the image rim
    services (lisp/lib/control.ml, [Control.run_with_rim]). Where the
    image services [Prim_call(name, args)] from the in-process store
    prim table, the proxy rim forwards every prim call that is not a
    local pure prim to the server via [transport] (POST /api/prim) and
    [continue]s with the deserialized value -- or [discontinue]s with
    the re-raised exception (reconstructed by Prims_pure.error_of_json)
    so a remote client observes identical exceptions to an in-process
    eval.

    PROXY DISCIPLINE (spec): the rim is a PURE proxy with zero
    interpretation logic. The only allowed local behavior is "dispatch
    to a local pure prim table" or "forward to /api/prim". Nothing in
    between -- the moment it grows its own meaning for a prim there are
    two dialects.

    NOTE on Control.direct_prims: the image sets it so nested eval
    inside a prim body dispatches by direct table lookup (its table is
    TOTAL there). Here the local table (pure prims only) is
    INTENTIONALLY partial, so setting direct_prims to it would make
    every DB/other prim raise "unregistered primitive" instead of
    proxying. We therefore leave direct_prims empty and let the
    Effect.Deep handler intercept EVERY [Prim_call]; the local/proxy
    split happens in the handler, not in direct_prims. This is safe
    because no local pure prim performs a nested eval from within a
    handler body (the case direct_prims exists to serve).

    The [transport] boundary is what makes the rim unit-testable: the
    Eio HTTP transport (remote/lib/http.ml) is swapped for a mock in
    the tests, so no live server is required. *)

open Pricklypear_lisp
open Ast
module Effect = Stdlib.Effect

291 remote/lib/remote.ml

```
(** remote/lib/remote.ml (borge/remote-eval.borg client).

    The client host: a pure-lisp env + a small LOCAL table of pure
    prims (shared Prims_pure code, so semantics are identical to the
    image's) + a [Proxy_rim.transport] to the image. All evaluation
    runs under the proxy rim; pure compute stays local, everything
    else proxies.

    LAZY ENV (spec): function resolution is data (the server's CTE
    over function_defs). The client materializes defs on first
    reference instead of at boot: an [Interp_error (Unbound_var name)]
    during eval triggers a fetch of the def source (via the
    [function-source] prim, proxied) and evals it into the env under
    the proxy rim, then retries the expression once. The env is a
    CACHE of definitions -- never a source of truth.

    IDENTITY: the client passes basic-auth per prim call through the
    transport. It never claims an author it does not hold; identity is
    server-asserted (whoami/current-author come back from the server). *)

292 remote/lib/surface.ml

```
(** pp-remote Nopales surface (borge/remote-eval.borg surfaces +
    agent-loop).

    The browser surface served by [Http_ui.serve] is NOPALES-AUTHORED
    htmx fragments on the client route table, rendered by Nopales via
    [libs/html] -- NOT compiled OCaml pages. The surface is redefinable
    live (same env as the REPL): re-evaluating a `(define chat/page ?)`
    at the REPL changes the next render without a restart. This is the
    faithful version of the agent's surface thesis, ported to the
    client: the route table + template dispatch are env-only and run
    unchanged under the proxy rim.

    Routes:
      /        -- chat page. POST /chat (OCaml-handled multipart stream)
                  runs the SHARED agent loop locally: provider call on
                  this machine, tool bodies under the proxy rim (DB prims
                  cross to the image). Fragment templates
                  (chat/user-bubble, chat/turn-open, chat/token, ...) are
                  Nopales, same names as the agent's so they transfer.
      /eval    -- eval box. POST /eval (OCaml-handled) calls Remote.eval
                  and renders the result via the Nopales eval/result
                  template.
      /code    -- lens browser. Lists lens nodes (lens/list) and reads
                  one (lens/read). Shows "no lens" when --lens is absent.

    The chat stream emitter + eval POST handler and the HTTP accept
    loop stay OCaml (per the surfaces scope: bootstrap/transport
    plumbing is OCaml); the PAGES and fragment templates are Nopales. *)

open Pricklypear_lisp

(** The surface source. Defines chat/page + the chat/* fragment
    templates, eval/page, eval/result, code/page, code/rows and registers
    the /, /eval and /code routes via the client route table. Uses
    libs/html + the client's request-shape prims (query-param) + the
    lens-browsing prims (lens/list, lens/read). The chat fragment
    templates carry the same names/shapes as the agent's
    (agent/lib/surface.ml) so a restyling transfers between hosts. *)

293 remote/lib/sync_client.ml

```
(* remote/lib/sync_client.ml -- borge/local-first.borg sync, the CLIENT
   half of the exchange (the git protocol in miniature, one round).

   A round: build the client's data (path, hash) manifest from the lens
   substrate, send it to the image's sync/push prim (with the recorded
   base manifest from the last successful round -- three-way), apply the
   response (pull server copies, mirror server deletions, print the
   surfaced LWW resolutions), and pin the merged state as the NEXT
   round's base. The server is the merge authority; the client is a
   governed branch rendezvousing with it.

   Invisibility is the common case: a quiet round (nothing to transfer,
   nothing diverged) prints nothing. Every divergence resolution --
   client-won or server-kept -- is a printed line (the obituary rule
   applies to sync losses). This module is the machinery --sync runs
   once and --sync-loop runs on a timer (the "background" in
   "sync invisibly in the background" is client-side scheduling of these
   rounds; no new server surface is needed). *)

294 remote/test/def_cache_test.ml

```
(** Tests for borge/remote-eval.borg caching subsection. No network --
    the [Proxy_rim.transport] is a mock serving the two proxyable read
    prims the def cache reads: [current-branch] (VStr, branch namespace)
    and [gen-now] (VInt, migration-017 branch_generations = the tree-time
    gen coordinate).

    Covers the three verification cases:
      1. a write in the client's branch ancestry bumps the generation;
         the next cache-check round trip observes the bump and reloads
         affected defs (the stale def is returned for eviction and
         dropped from the table, so the next lookup misses -> re-fetch).
      2. a checkout to a different branch invalidates the WHOLE local
         def cache (branch is the namespace).
      3. with no writes, the cache-check round trip is the single cheap
         HEAD-ish (two single-counter reads) returning unchanged-
         generation -- it does NOT do an N-way hash diff and mutates
         nothing.
    Plus a client-integration case: the lazy env re-fetches a def once
    the generation bumps (the [function-source] prim is called again and
    the NEW source is what eval uses). *)

295 remote/test/free_vars_test.ml

```
(** Tests for remote/lib/free_vars.ml -- free-variable analysis over a
    Nopales AST. Pure (no I/O, no env); mirrors the worker's purity.

    The reader produces special forms as [App(Var "lambda", ?)] (eval
    desugars later), so the walker must dispatch on those App forms --
    binding lambda params / let names so they aren't mistaken for deps,
    treating quote bodies as data, and skipping kernel special-form
    names. These tests pin that behavior against the reader's actual
    output (not hand-built AST). *)

296 remote/test/lens_store_test.ml

```
(** Tests for borge/local-first.borg lens-model + replication-units +
    local-substrate (the remote/lib/lens_store.ml module). No network, no
    Postgres -- pure filesystem + JSON, mirroring how the worker itself is
    pure.

    Verifies the pinned contracts from the campaign 8.0 plan pass:
      - fork_lens_name produces <owner>/lens-<device>[-<date>] (lens-model
        fork naming for the (fork ...)/Store.fork_branch child branch).
      - in_replication_unit confines replication to exactly the
        authorized-read subtree: data.u.<user>.* (full), data.shared.*
        (read-mostly seed), b.<lens>.* (the forked code lens) - and NOTHING
        outside it (another user's data.u.<other>.* never replicates, the
        one-tree path-prefix RLS floor is the replication boundary).
      - the substrate (local-substrate): materialize writes one node
        envelope file per node at its path under the lens root; get /
        subtree_list are the path-addressed reads (the filesystem IS the
        path index); put_body + node_hash are the local write path whose
        content hash is the sync/three-way-diff key. *)

```
; navbar editor -- WYSIWYG drag-and-drop navbar rearrangement (PoC spike)
; ------------------------------------------------------------------------
; storage: one data_rows row of type navbar-config, field "items" = JSON
; of the menu item tree. item shapes (same contract as menu/render):
;   ("link" label href) | ("group" label (kids ...)) | ("raw" html "")
; the chip bar reuses menu/render + scoped copies of the chrome nav CSS,
; so the editor IS the navbar (WYSIWYG). drag reorder + delete post via
; fetch (HX-Request header -> fragment response); add/reset use htmx.
; after every mutation the fragment carries a hidden #nbed-realnav div
; with the fresh (menu/bar (navbar/items)) so JS can live-update the
; real header navbar without a reload; (checkout (current-branch)) in
; each handler also resets the 60s ui_shell cache for other pages.
;
; load:   python3 scripts/pp_eval.py < spikes/navbar-editor/lib.pp
